### (57) ABSTRACT

The invention relates to the isolation and characterization of a maize gene, RAMOSA3 (RA3), responsible for meristem development and inflorescence development including branching. The gene, gene product, and regulatory regions may be used to manipulate branching, meristem growth, inflorescence development and arrangement, and ultimately to improve yield of plants. The invention includes the gene and protein product as well as the use of the same for temporal and spatial expression in transgenic plants to alter plant morphology and affect yield in plants. The invention also includes the gene and protein product for SISTER OF RAMOSA3 (SRA).

### NUCLEOTIDE SEQUENCES ENCODING RAMOSA3 AND SISTER OF RAMOSA3 AND METHODS OF USE FOR SAME

This application is a continuation of U.S. patent application Ser. No. 13/288,987, filed Nov. 4, 2011, now U.S. Pat. No. 8,410,257, issued Apr. 2, 2013, which is a continuation of U.S. patent application Ser. No. 13/042,531, filed Mar. 8, 2011, now U.S. Pat. No. 8,076,141, issued Dec. 13, 2011, which is a divisional of U.S. patent application Ser. No. 12/498,699, filed Jul. 7, 2009, now U.S. Pat. No. 7,915,045, issued Mar. 29, 2011, which is a divisional of U.S. patent application Ser. No. 11/942,036, filed Nov. 19, 2007, now U.S. Pat. No. 7,588,939, issued Sep. 15, 2009, which is a divisional of U.S. patent application Ser. No. 11/327,740, filed Jan. 6, 2006, now U.S. Pat. No. 7,314,758, issued Jan. 1, 2008, which claims the benefit of U.S. Provisional Application No. 60/642,273, filed Jan. 7, 2005, and U.S. Provisional Application No. 60/739,857, filed Nov. 23, 2005, each of which is hereby incorporated by reference in its entirety.

### GOVERNMENT SUPPORT

The invention described herein was made in whole or in part with government support under USDA Award No. 2005-02402 and NSF Award No. DBI-0110189 awarded by the United States Department of Agriculture and the National Science Foundation, respectively. The United States Government has certain rights in the invention.

### REFERENCE TO SEQUENCE LISTING SUBMITTED ELECTRONICALLY

The official copy of the sequence listing is submitted electronically via EFS-Web as an ASCII formatted sequence listing with a file named "20130305\_BB1552USCNT2\_ SeqLst.txt" created on Feb. 19, 2013, and having a size of 105 kilobytes and is filed concurrently with the specification. The sequence listing contained in this ASCII formatted document is part of the specification and is herein incorporated by reference in its entirety.

### FIELD OF THE INVENTION

The field of invention relates generally to plant molecular <sup>45</sup> biology, and more specifically, to protein and nucleotide sequences and genetic techniques using the same to modify plant architecture and to increase yield and health of plants.

### BACKGROUND OF THE INVENTION

Plant architecture is central to yield, for example in orchestrating the green revolution through reducing plant height [Peng, J. et al., Nature, 1999. 400(6741): p. 256-611]. Similarly, inflorescence morphology is a major yield factor in 55 many crops, and is determined by the activities of shoot meristems. Variations in branching patterns lead to diversity in architectures, and have been studied at the genetic, physiological and molecular levels [Sussex, I. M. and Kerk, N. M., Curr Opin Plant Biol, 2001. 4(1): p. 33-7; Ward, S. P. and 60 Leyser, O., Curr Opin Plant Biol, 2004, 7(1): p. 73-8].

### Factors that Control Shoot Branching

The shoot apical meristem (SAM) is active throughout the 65 plant lifecycle, and produces leaves and axillary meristems, typically initiated in each leaf axil. Patterns of axillary mer-

2

istem activity—where they are produced, whether they undergo dormancy or growth and how much they grow—contribute to overall shoot architecture. Apical dominance is a major factor in regulating development of axillary meristems, and is regulated by genetic and hormonal factors.

Development of axillary meristems can be described in two phases, initiation and growth.

Genes like REVOLUTA (REV) and LATERAL SUP-PRESSOR (LAS) in *Arabidopsis* are involved in initiation.

10 rev mutants often fail to produce axillary meristems during both vegetative and reproductive development. REV encodes a homeodomain/leucine zipper transcription factor and is expressed in very early axillary meristems. On the other hand, in las mutants, defects in formation of axillary meristems occur only during vegetative development. LAS is however expressed in leaf axils during both vegetative and reproductive development. LAS also encodes a transcriptional factor, a member of the GRAS family. Expression patterns suggest that LAS acts upstream of REV in axillary meristem development.

The maize teosinte branched1 (tb1) locus is another well-characterized regulator of axillary meristem growth. The tb1 mutant phenotype resembles the maize ancestor, teosinte, in axillary meristem outgrowth. QTL analysis, gene structure and expression analyses indicate that TB1 is one of the major genes involved in the important change of plant architecture involved in the development of maize as a crop. The rice TB1 ortholog appears to act downstream of the rice LAS ortholog, monoculm1.

The regulation of axillary meristem outgrowth is complex, and several genes, as well as the hormones, auxin, cytokinin and abscisic acid (ABA) have been implicated. Auxin is traditionally thought of as an inhibitor of axillary meristem growth, though recent evidence suggests that it also functions during axillary meristem initiation. The importance of auxin for growth is suggested by the fact that auxin resistant 1 (axr1) mutants, which have reduced responses to auxin, are highly branched. However, the concentrations of auxin in axillary meristems after decapitation are sometimes higher than before, and auxin appears to act non-autonomously, in the xylem and interfascicular schlerenchyma, to suppress branching. This suggests the existence of mobile second messengers that transmit the auxin signal.

One candidate is for such a signal is a cytokinin. Cytokinins can promote the growth of axillary meristems following direct application, and auxin can down-regulate cytokinin biosynthesis. Further evidence of a role for cytokinin in axillary meristem growth comes from analysis of the *Arabidopsis* hoc and supershoot mutants, which have higher endogenous cytokinin levels and an extremely branched phenotype. Physiological and genetic analyses suggest that the hormone abscisic acid may also regulate the growth of axillary meristems

Genetic analysis is also beginning to identify novel branching signals. ramosus (rms) mutants in pea and more axillary growth (max) mutants in *Arabidopsis* have a bushy phenotype and auxin resistant bud growth. Grafting experiments, hormone measurements and responses of these mutants to auxin strongly suggested the existence of a novel mobile branchinhibition signal that functions downstream of auxin. Recent cloning of MAX3 and MAX4 has started to provide some clues as to the nature of this signal. Both genes encode proteins related to dioxygenases, and the hypothesis is that the signal is derived by cleavage of a carotenoid. Analysis of other rms and max mutants has revealed other genes that are not rescued by grafting, and may function in MAX/RMS-dependent signal perception. The fact that MAX2 encodes an

F-box protein may match the hypothesis, since many such proteins are involved in hormone regulation.

### Factors that Control Inflorescence Branching

Internal and environmental stimuli promote the transition from vegetative SAM to inflorescence meristem (IM), which initiates the inflorescence structures. In grasses, inflorescence development is characterized by the formation of short branches called spikelets. Maize forms two distinct types of inflorescence; the terminal tassel has long branches and develops the male flowers, and the axillary ears have a prominent axis lacking long branches, and develop female flowers. The IM initiates files of spikelet pair meristems (SPMs), and each SPM in turn produces two spikelet meristems (SMs), which initiates two floral meristems (FMs). In the tassel, the IM also initiates several branch meristems (BMs), which are responsible for the long branches at the base of the tassel, followed by SPMs, SMs and FMs as in the ear.

Inflorescence architecture in different species is highly variable, for example in contrast to maize, rice has only one kind of bisexual inflorescence formed from apical and axillary meristems. Each IM produces primary branches in a spiral phyllotaxy, and these make secondary branches and 25 SMs in a biased distichous phyllotaxy. Both primary and secondary branch meristems (BMs) in rice correspond to SPMs in maize inflorescences, from the viewpoint that they initiate SMs. The rice IM degenerates after making primary BMs, and the internodes of both primary and secondary 30 branches elongate to form a panicle architecture, which looks very different from that of maize, though their structural components are essentially the same.

Several genes that regulate maize and rice inflorescence branching and morphology have been identified. BARREN 35 INFLORESCENCE2 (BIF2) and BARREN STALK1 (BA1) in maize, and LAX PANICLE (LAX) in rice control the initiation of axillary Ns. bif2 tassels make fewer or no branches and spikelets, and the ears have fewer or no spikelets. Since the BMs, SPMs, SMs and FMs in weak bif2 40 mutants are all defective, it appears that BIF2 is required for initiation and maintenance of all types of axillary meristems. bal mutants lack vegetative axillary branches and ears, and have unbranched tassels lacking spikelets. In rice lax mutants, the number of primary branches and spikelets is also strongly 45 reduced. These phenotypes indicate that both BA1 and LAX are required to initiate inflorescence axillary meristems. They encode orthologous basic helix-loop-helix transcription factors, and are expressed at the boundaries between pre-existing and newly initiated axillary meristems. These localized 50 expression patterns support the functions of LAX and BA1 in the production of axillary meristems, and suggest that the gene functions are strongly conserved between rice and maize. Zea floricaula/leafy (zfl) mutants in maize also have less tassel branches and fewer ear row numbers in addition to 55 defects during the inflorescence transition.

Once axillary meristems are initiated, they acquire new identities. RAMOSA1 (RA1) in maize is required in the tassel and ear for the transition from SPM to SM identity, and ra1 mutants have highly branched inflorescences [Postlethwait, 60 S. N. and Nelson, O. E., Characterization of development in maize through the use of mutants. I. The polytypic (Pt) and ramosa-1 (ra1) mutants. Am. J. Bot., 1964. 51: p. 238-243; Vollbrecht et al. Nature 436:1119-1126].

Ramosa2 (ra2) mutants have a similar phenotype to ra1 65 except that in ra2 the pedicellate spikelet is converted to a branch. Nickerson, N. H. et al., Tassel modifications in *Zea* 

4

mays. Ann. MO Bot. Gard., 42, 195-211 (1955); Hayes, H., Recent linkage studies in maize. IV. Ramosa ear-2 (ra2). Genetics, 1939. 24: p. 61.

Ramosa3 (ra3) is a classical mutant of maize, first described in 1954 [Perry, H. S., Unpubished, http://www.maizegdb.org/. 1954] (see also, Table 1 of Veit et al. Plant Cell 5:1205-1215 (1993)), but it has not been characterized in detail. Only the mature inflorescence phenotype has been reported.

In tassel seed4 (ts4) mutants most SPMs in the tassel and those on the distal part of the ear reiterate SPMs, therefore TS4 is required for SM identity. FRIZZY PANICLE (FZP) in rice and BRANCHED SILKLESS1 (BD1) in maize regulate meristem identity at the transition from SMs to FMs. fzp and bd1 mutants produce branching structures without making flowers, so these genes are required to regulate the determinacy of SMs and/or to establish the identity of FMs. FZP and BD1 encode orthologs in the ethylene-responsive element-binding factor class of transcription factors. They are expressed in analogous patterns at the junction of SMs and rudimentary glumes in rice, and SMs and inner/outer glumes in maize. Therefore some genes that regulate inflorescence architecture in rice and maize are strongly conserved in function and expression pattern.

Other genes regulating SM determinacy include the maize REVERSED GERM ORIENTATION1 (RGO1), INDETERMINATE SPIKELET1 (IDS1), INDETERMINATE FLORAL APEX1 (IFA1) and TASSEL SEED6 (TS6) genes. In these mutants, the SMs become more indeterminate, and produce extra flowers. The degree of SPM and SM determinacy is one of the characteristic variables in grass inflorescence architecture, and differs significantly between rice and maize, as described above, and in other grasses, for example, in wheat, the SMs are indeterminate.

Genetic and molecular analyses in model species have contributed to understanding the mechanisms of inflorescence branching in the grasses. Most of the genes that have been isolated encode putative transcription factors, suggesting they regulate the transcription of downstream targets.

### Trehalose Biology and Signaling

Trehalose is a disaccharide composed of two glucose units. It is highly resistant to heat and pH and has a strong stabilizing effect on proteins. In contrast to sucrose, which is present only in the plant kingdom and some photosynthetic prokaryotes, trehalose is present in all kingdoms and plays a role in carbohydrate storage and stress protection in microbes and invertebrates. See, e.g., Goddijn, O. J. and van Dun, K., Trehalose metabolism in plants. Trends Plant Sci, 1999. 4(8): p. 315-319; Elbein, A. D., The metabolism of a,a-trehalose. Adv. Carbohydr. Chem. Biochem., 1974. 30(227-56.); Crowe, J. H., Hoekstra, F. A., and Crowe, L. M., Anhydrobiosis. Annu Rev Physiol, 1992. 54: p. 579-99; Strom, A. R. and Kaasen, I., Trehalose metabolism in Escherichia coli: stress protection and stress regulation of gene expression. Mol Microbiol, 1993. 8(2): p. 205-10; and Paiva, C. L. and Panek, A. D., Biotechnological applications of the disaccharide trehalose. Biotechnol Annu Rev, 1996. 2: p. 293-314.

Until recently trehalose was not thought to be present in vascular plants, with the exception of desiccation-tolerant plants (reviewed in Muller, J., Boller, T., and Wiemken, A., Trehalose and trehalase in plants: recent developments. Plant Sci., 1995. 112: p. 1-9).

However, interest in the application of engineering trehalose metabolism to produce drought tolerant crops led to the discovery of trehalose biosynthetic genes in plants. See, e.g.,

Holmstrom, K. O., Mantyla, E., Welin, B., Mandal, A., and Palva, E. T., Drought tolerance in tobacco. Nature, 1996. 379: p. 683-684; Romero, C., Belles, J. M., Vaya, J. L., Serrano, R., and Cilianez-Macia, A., Expression of the yeast trehalose-6phosphate synthase gene in transgenic tobacco plants: pleio- 5 tropic phenotypes include drought tolerance. Planta, 1997. 201: p. 293-297; and Garg, A. K., Kim, J. K., Owens, T. G., Ranwala, A. P., Choi, Y. D., Kochian, L. V., and Wu, R. J., Trehalose accumulation in rice plants confers high tolerance levels to different abiotic stresses. Proc Natl Acad Sci USA, 10 2002. 99(25): p. 15898-903. See also, e.g., Goddijn, O. J., Verwoerd, T. C., Voogd, E., Krutwagen, R. W., de Graaf, P. T., van Dun, K., Poels, J., Ponstein, A. S., Damm, B., and Pen, J., Inhibition of trehalase activity enhances trehalose accumulation in transgenic plants. Plant Physiol, 1997. 113(1): p. 181-15 90; Muller, J., Aeschbacher, R. A., Wingler, A., Boller, T., and Wiemken, A., Trehalose and trehalase in Arabidopsis. Plant Physiol, 2001. 125(2): p. 1086-93; Vogel, G., Fiehn, O., Jean-Richard-dit-Bressel, L., Boller, T., Wiemken, A., Aeschbacher, R. A., and Wingler, A., Trehalose metabolism in Ara-20 bidopsis: occurrence of trehalose and molecular cloning and characterization of trehalose-6-phosphate synthase homologues. J Exp Bot, 2001. 52(362): p. 1817-26; and Leyman, B., Van Dijck, P., and Thevelein, J. M., An unexpected plethora of trehalose biosynthesis genes in Arabidopsis 25 thaliana. Trends Plant Sci, 2001. 6(11): p. 510-3.

N-terminal deletion of the *Selaginella lepidophylla* (a "resurrection plant") or *Arabidopsis thaliana* trehalose-6-phosphate synthase (TPS1) results in a dramatic increase in TPS activity (Van Dijck et al., 2002, *Biochem. J.* 366:63-71). This 30 indicates a high potential trehalose synthesis capacity in plants in spite of the near universal absence of trehalose.

The biosynthesis of trehalose occurs in 2 steps, analogous to that of sucrose. Trehalose-6-phosphate (T6P) is first formed from UDP-glucose and glucose-6-phosphate by trehalose-6-phosphate synthase (TPS). Next, T6P is converted to trehalose by trehalose-6-phosphate phosphatase (TPP).

Trehalose metabolism has been analyzed in detail in *Saccharomyces cerevisiae* and *Escherichia coli*. In *S. cerevisiae*, TPS1 is responsible for TPS activity, and TPS2 for TPP activity, and they function in a complex together with regulatory subunits encoded by TPS3 and TSL1 [Londesborough, J. and Vuorio, O., Trehalose-6-phosphate synthase/phosphatase complex from bakers' yeast: purification of a proteolytically activated form. J Gen Microbiol, 1991. 137 (Pt 2): p. 323-30; Bell, W., Sun, W., Hohmann, S., Wera, S., 45 Reinders, A., De Virgilio, C., Wiemken, A., and Thevelein, J. M., Composition and functional analysis of the *Saccharomyces cerevisiae* trehalose synthase complex. J Biol Chem, 1998. 273(50): p. 33311-9].

However in E. coli, OtsA, which has TPS activity, and 50 OtsB, which has TPP activity, act independently. In Arabidopsis, more than ten homologues have been found for both TPS and TPP genes. Functional analysis of the plant genes has concentrated on the Arabidopsis TPS1 gene. Loss-offunction tps1 mutants are embryo lethal, and were not rescued by exogenous trehalose. The tps1 mutants can be rescued by an inducible TPS1 construct, but have reduced root growth, and continued induction is required for the transition to flowering. Plants over-expressing AtTPS1 had increased dehydration (drought) tolerance and were glucose- and ABA-insensitive [Avonce, N., Leyman, B., Mascorro-Gallardo, J. O., Van Dijck, P., Thevelein, J. M., and Iturriaga, G., The Arabidopsis trehalose-6-P synthase AtTPS1 gene is a regulator of glucose, abscisic acid, and stress signaling. Plant Physiol, 2004. 136(3): p. 3649-59].

*Arabidopsis* also encodes a number of TPP homologs, 65 encoding proteins with a TPP domain, with highly conserved phosphatase motifs typical of this class of phosphohydrolases

6

[Thaller, M. C., Schippa, S., and Rossolini, G. M., Conserved sequence motifs among bacterial, eukaryotic, and archaeal phosphatases that define a new phosphohydrolase superfamily. Protein Sci, 1998. 7(7): p. 1647-52].

Arabidopsis TPP genes were first isolated by their ability to complement yeast tps2 mutants [Leyman, B., Van Dijck, P., and Thevelein, J. M., An unexpected plethora of trehalose biosynthesis genes in Arabidopsis thaliana. Trends Plant Sci, 2001. 6(11): p. 510-3; Vogel, G., Aeschbacher, R. A., Muller, J., Boller, T., and Wiemken, A., Trehalose-6-phosphate phosphatases from Arabidopsis thaliana: identification by functional complementation of the yeast tps2 mutant. Plant J, 1998. 13(5): p. 673-83], though no other information is available on the biological functions of these genes.

Trehalose-6-phosphate has also recently emerged as a regulator of carbon metabolism, and appears to act as an enhancer of photosynthetic capacity through interaction with sugar signaling pathways. Plants over-expressing either the bacterial or yeast trehalose biosynthetic genes have altered carbohydrate metabolism, and some morphological defects. These phenotypes are thought to result from changes in carbon allocation between sink and source tissues and provoked speculation that trehalose metabolism may be involved in sugar signaling. Paul et al. (Enhancing photosynthesis with sugar signals. Trends Plant Sci, 2001. 6(5): p. 197-200) reasoned that T6P could be the signal that allows hexokinase to perceive carbon status, as is the case in yeast. However this is inconsistent with the fact that T6P is not an inhibitor of Arabidopsis hexokinases AtHXK1 and AtHXK2 in vitro, and reducing hexokinase activity did not rescue the growth of Arabidopsis tps1 embryos. Nevertheless, an analysis of Arabidopsis plants over-expressing OtsA, OtsB and treC (trehalose phosphate hydrolase) also confirms an involvement of T6P in carbohydrate utilization and growth via control of glycolysis.

Trehalose signaling also appears to play a similar role in monocots, since transgenic rice overexpressing *E. coli* OtsA and OtsB had increased trehalose accumulation, and this correlated with more soluble carbohydrates and a higher capacity for photosynthesis under both stress and non-stress conditions. These results are consistent with a role for the trehalose pathway in modulating sugar sensing and carbohydrate metabolism.

In addition to T6P, other signaling steps in the plant trehalose pathway have been proposed. For example, the TPS protein interacts with regulatory 14-3-3 proteins, and this interaction may depend on the cellular sugar status. Trehalose itself may also act as a signal, although it is unlikely to act as an osmoprotectant as in microbes as the concentration is very low. However, a possible target of trehalose is ApL3, an ADP-glucose pyrophosphorylase, which is involved in starch biosynthesis. These data suggest that trehalose interferes with carbon allocation to the sink tissues by inducing starch synthesis in source tissues.

While exact roles of trehalose and related sugars is not clearly understood, sugars in general are thought of as signaling molecules or as global regulators of gene expression. In addition to their obvious metabolic functions, sugars can act like hormones, or can modulate hormone signaling pathways.

### SUMMARY OF THE INVENTION

The Present Invention Includes:

An isolated polynucleotide comprising: (a) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant transformed with said isolated polynucleotide results in alteration of the

branching of the tassel, ear, or both, of said transformed plant when compared to a control plant not comprising said isolated polynucleotide; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, expression of said polypeptide results in a decrease in the branching of the tassel, ear, or both, and even more preferably, the plant is maize.

An isolated polynucleotide comprising: (a) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant transformed with said isolated polynucleotide results in alteration of pollen shed of said transformed plant when compared to a control plant not comprising said isolated polynucleotide; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, expression of said polypeptide results in a decrease in pollen shed, and even more preferably, the plant is maize.

An isolated polynucleotide comprising: (a) a nucleotide 25 sequence encoding a polypeptide associated with branching of the tassel, ear, or both, of a plant (preferably maize), wherein said polypeptide has an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary.

An isolated polynucleotide comprising: (a) a nucleotide 35 sequence encoding a polypeptide associated with pollen shed of a plant (preferably maize), wherein said polypeptide has an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID 40 NO:19, or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary.

An isolated polynucleotide comprising: (a) a nucleic acid 45 sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant exhibiting a 50 ramosa3 mutant phenotype results in an decrease of branching of the tassel, ear, or both of the plant; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, the plant is 55 maize.

An isolated polynucleotide comprising: (a) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V 60 method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant exhibiting a ramosa3 mutant phenotype results in an decrease of pollen shed of the plant; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, the plant is maize.

8

An isolated polynucleotide comprising: (a) a nucleic acid sequence encoding a polypeptide having trehalose-6-phosphate phosphatase activity, wherein the polypeptide has an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary.

Any recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in said plant, wherein said polynucleotide comprises an isolated polynucleotide of the present invention.

A vector comprising a polynucleotide of the present invention.

A suppression DNA construct comprising a promoter functional in a plant operably linked to (a) all or part of (i) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 50% sequence identity, or any integer up to and including 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69, or (ii) a full complement of the nucleic acid sequence of (a)(i); (b) a region derived from all or part of a sense strand or antisense strand of a target gene of interest, said region having a nucleic acid sequence of at least 50% sequence identity, based on the Clustal V method of alignment, when compared to said all or part of a sense strand or antisense strand from which said region is derived, and wherein said target gene of interest encodes a RAMOSA3 (RA3) polypeptide or a SISTER OF RAMOSA3 (SRA) polypeptide; or (c) a nucleic acid sequence of at least 50% sequence identity, or any integer up to and including 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:15, 18, 47, 48, or 67. The suppression DNA construct preferably comprises a cosuppression construct, antisense construct, viral-suppression construct, hairpin suppression construct, stem-loop suppression construct, double-stranded RNA-producing construct, RNAi construct, or small RNA construct (e.g., an sRNA construct or an miRNA construct).

A plant comprising in its genome a recombinant DNA construct of the present invention.

A plant whose genome comprises a disruption (e.g., an insertion, such as a transposable element, or sequence mutation) of at least one gene (which may be heterologous or endogenous to the genome) encoding at least one polypeptide selected from the group consisting of a RAMOSA3 (RA3) polypeptide or a SISTER OF RAMOSA3 (SRA) polypeptide.

Any progeny of the above plants, and any seed obtained from the plant or its progeny. Progeny includes subsequent generations obtained by self-pollination or out-crossing of a plant. Progeny also includes hybrids and inbreds.

A method for altering branching of the tassel, ear, or both, of a plant, comprising: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce a transformed plant cell, said recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in a plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19; and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an

alteration in branching of the tassel, ear, or both, when compared to a control plant not comprising said recombinant DNA construct. The method may further comprise (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct. Preferably, the transgenic plant or progeny thereof exhibits a decrease in branching of the tassel, ear, or both.

A method for altering pollen shed of a plant, comprising: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce a transformed plant cell, said recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in a plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19; and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said recombinant DNA construct and 20 wherein said transgenic plant exhibits an alteration in pollen shed, when compared to a control plant not comprising said recombinant DNA construct. The method may further comprise (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its 25 genome the recombinant DNA construct. Preferably, the transgenic plant or progeny thereof exhibits a decrease in pollen shed.

A method for altering trehalose-6-phosphate phosphatase activity in a plant, comprising: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce a transformed plant cell, said recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in a plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at 35 least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69; and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant com- 40 prises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an alteration in trehalose-6-phosphate phosphatase activity, when compared to a control plant not comprising said recombinant DNA construct. The method may further comprise (c) obtaining a 45 progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct. Preferably, the transgenic plant or progeny thereof exhibits an increase in trehalose-6-phosphate phosphatase activity.

A method for increasing environmental stress tolerance (preferably drought tolerance) of a plant, comprising: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce a transformed plant cell, said recombinant DNA construct comprising a polynucleotide operably 55 linked to a promoter that is functional in a plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ 60 ID NO:19, 49, 68 or 69; and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an increase in environmental stress tolerance (preferably 65 drought tolerance), when compared to a control plant not comprising said recombinant DNA construct. The method

10

may further comprise (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct.

### BRIEF DESCRIPTION OF THE FIGURES AND SEQUENCE LISTING

The invention can be more fully understood from the following detailed description and the accompanying drawings and Sequence Listing which form a part of this application.

FIG. 1A-FIG. 1D show the mature ear and tassel phenotypes of ra3 mutants. Wild-type ear (FIG. 1A) has nicely arranged rows and no long branches, whereas ra3 mutant ears (FIG. 1B) have long branches and irregular rows of kernels. Occasionally, ra3 ears are covered in long branches (FIG. 1B, right). Wild-type tassels normally have long branches at their base (FIG. 1C), and ra3 mutant tassels (FIG. 1D) have more branches.

FIG. 2A-FIG. 2H show the SEM analysis of ra3 mutant ears. Wild type (B73) ears are shown in FIG. 2A-FIG. 2D, and ra3 ears in FIG. 2E-FIG. 2H. During the inflorescence transition stage, there is no difference between B73 (FIG. 2A) and ra3 mutant (FIG. 2E) ears. In 2 mm long ears, some SPM converted to BM\* (FIG. 2F, arrow 1). SMs in B73 produce a pair of glumes (FIG. 2C, arrows 2), but in ra3 they produce additional glumes (FIG. 2G, arrows 2), and FMs were made inside the glumes (arrow 3). The SMs in wild type ears make 2 FMs inside the glumes (FIG. 2D, upper FM marked by arrow 3) and each floret has a lemma and palea (FIG. 2D, palea marked by arrow 4). The SMs in ra3 mutants make several FMs (arrows 3, FIG. 2H, palea marked by arrow 4) and later can convert to a BM\* that makes glumes (FIG. 2H, arrows 2). Scale bars FIG. 2A, FIG. 2E 100 µm; FIG. 2B, FIG. 2F 500 μm; FIG. 2C, FIG. 2D 100 μm; FIG. 2G, FIG. 2H 200

FIG. 3 shows a schematic of wild type (wt) and ra3 ear development. BM\* indicates a meristem which makes SPMs. SPM\* indicates a meristem which makes SMs. SM\* indicates meristem which makes FMs.

FIG. 4A-FIG. 4B show a map of the RA3 locus. The position of the RA3 and related SRA loci on BAC clone c0387K01 is given in (FIG. 4A). Marker positions are shown as black dots and number of recombinants for each is shown. The RA3 gene structure is given in (FIG. 4B). The shaded box immediately preceding the start ATG codon and the shaded box immediately following the stop codon each represent UTRs; the shaded boxes in between these UTRs indicate coding sequence; and "TATA" indicates the predicted TATA-box.

FIG. 5A-FIG. 5B show the predicted RA3 protein structure and phylogenetic analysis. The RA3 protein structure is shown in FIG. 5A. The TPP similarity regions are labeled "2". the phosphatase boxes are labeled "3", and the non-conserved regions are labeled "1". The neighbor joining tree is shown in FIG. 5B, using Phylogenetic Analysis Using Parsimony ("PAUP"; SWOFFORD D.L., (1993) J Gen Physiol 102:A9) of the conserved part of the TPP region of RA3-like proteins in maize, rice and Arabidopsis. Maize proteins are the following: RA3, SRA, ZmRA3L1-8. Rice proteins are the folgi37806433, gi33146623, gi46390128, lowing: 9631.m02649, 9683.m03678, 9634.m01158. Arabidopsis proteins are the following: At5g51460, At1g35910, At2g22190, At4g39770, At5g10100, At5g65140.

FIGS. 6A, 6B, 6C and 6D show a sequence alignment of the following amino acid sequences: (1) SEQ ID NO:19, for the corn RAMOSA3 polypeptide; (2) SEQ ID NO:49, for the corn SISTER OF RAMOSA3 polypeptide; (3) SEQ ID

NO:51, for the rice trehalose-6-phosphate phosphatase polypeptide corresponding to NCBI GI NO. 33146623; (4) SEQ ID NO:52, for the Arabidopsis TPPA polypeptide corresponding to NCBI GI NO. 2944178; (5) SEQ ID NO:53, for the Arabidopsis TPPB polypeptide corresponding to NCBI 5 GI NO. 2944180; (6) SEQ ID NO:54, for a corn trehalose-6phosphate phosphatase polypeptide that is cited as SEQ ID NO:16 in U.S. Patent Publication 2004-0229364-A1; (7) SEQ ID NO:55, for a soybean trehalose-6-phosphate phosphatase polypeptide that is cited as SEQ ID NO:20 in U.S. 10 Patent Publication 2004-0229364-A1; (8) a truncated version of SEQID NO:52, in which the N-terminal 91 amino acids are removed; this fragment was shown to have enzymatic activity (Vogel et al. (1998) *Plant J* 13(5):673-683); and (9) a truncated version of SEQ ID NO:53, in which the N-terminal 91 amino acids have been removed. A consensus sequence of 414 amino acids was generated and is numbered below these nine sequences. The amino acid positions for each sequence is given to the left of each row, and to the right of the final row. An asterisk above an amino acid residue indicates that the 20 position is totally conserved among the given SEQ ID NOs, with respect to the *Arabidopsis thaliana* AtTPPB sequence. Below the sequences are shown two domains, A and B, that are conserved among trehalose-6-phosphate phosphatases, as described in Vogel et al. (1998) Plant J 13(5):673-683. The 25 primer. given sequence for each conserved domain is taken from the Arabidopsis thaliana AtTPPB amino acid sequence at these positions.

FIG. 7A-FIG. 7B show that RA3 expression is highest in developing inflorescences. In FIG. 7A is shown the RA3 30 expression in 1 cm ear primordia from B73 (lane 1) and ra3 alleles. In ra3-ref (lane 2) and ra3-feat (lane 3), very low expression was detected, while the level of expression in ra3-EV, ra3-NI and ra3-bre (lanes 4-6) was normal, except that the ra3-NI transcript is slightly larger, as it has a small 35 insertion (Table 2). The lower panel shows Ubiquitin (UBI) expression as a control. In FIG. 7B is shown the RA3, SRA and Ubiquitin expression during wild type (B73) development. The mRNAs were extracted from root (R), vegetative apex (V), young leaves (L) and ear or tassel inflorescence 40 primordia. The triangles represent increasing inflorescence size, from transition stage to ~1.5 cm ears and tassels. RA3 expression peaks in 2-5 mm inflorescences.

FIG. 8A-FIG. 8F show that RA3 expression is spatially restricted during ear development. RA3 was first expressed at 45 the base of SPMs (arrows, FIG. 8A). After that, RA3 expression enlarged to a cup-shaped domain at the base of SPMs and SMs (arrows, FIG. 8B, FIG. 8C and FIG. 8D). FIG. 8B and FIG. 8C are longitudinal median and glancing sections, respectively, and FIG. 8D is a transverse section. At later 50 stages, RA3 was expressed at the boundary between upper and lower florets (arrows, FIG. 8E). No RA3 transcript was detected in a ra3-ref ear (FIG. 8F), at similar stage to FIG. 8B.

FIG. 9 shows phosphate release, measured as OD<sub>600</sub>, following treatment of various phosphorylated substrates. For each substrate, shown left to right, respectively, is the activity due to each of the following proteins: 1) His-tagged RA3 full-length protein (SEQ ID NO:61); 2) His-tagged RA3 TPP-domain fragment (SEQ ID NO:62); 3) His-tagged RA3 N-terminal fragment (SEQ ID NO:63); 4) His-tagged Mycobacterium tuberculosis TPP (Edavana et al., Arch Biochem Biophys 426:250-257 (2004)); 5) shrimp alkaline phosphatase (SAP; Roche Applied Science); 6) no protein.

FIG. 10 shows growth of a yeast tps2 mutant (yeast strain YSH6.106.-8C) transformed with an RA3 protein, RA3 TPP-65 domain fragment, a positive control (Arabidopsis trehalose-6-phosphate phosphatase gene, AtTPPB), and a negative con-

12

trol (empty yeast vector). Transformed cells were assayed for growth on selective media at  $40.5^{\circ}$  C. in the presence of 1M NaCl, as well as at  $30^{\circ}$  C.

SEQ ID NO:1 is the nucleotide sequence of the csu597 forward primer.

SEQ ID NO:2 is the nucleotide sequence of the csu597 reverse primer.

SEQ ID NO:3 is the nucleotide sequence of the umc1412 forward primer.

SEQ ÎD NO:4 is the nucleotide sequence of the umc1412 reverse primer.

SEQ ID NO:5 is the nucleotide sequence of the a14 forward primer.

SEQ ID NO:6 is the nucleotide sequence of the a14 reverse  $\,$  primer.

SEQ ID NO:7 is the nucleotide sequence of the n20 forward primer.

SEQ ID NO:8 is the nucleotide sequence of the n20 reverse primer.

SEQ ID NO:9 is the nucleotide sequence of the cb.g1E forward primer.

SEQ ID NO:10 is the nucleotide sequence of the cb.g1E reverse primer.

SEQ ID NO:11 is the nucleotide sequence of the NS346 primer.

SEQ ID NO:12 is the nucleotide sequence of the NS347 primer.

SEQ ID NO:13 is the nucleotide sequence of the NS362 primer.

SEQ ID NO:14 is the nucleotide sequence of the NS363 primer.

SEQ ID NO:15 is the genomic nucleotide sequence containing the RAMOSA3 gene.

SEQ ID NO:16 is the nucleotide sequence of the NS432 forward primer used to amplify the cDNA containing the RAMOSA3 open-reading frame.

SEQ ID NO:17 is the nucleotide sequence of the NS411 reverse primer used to amplify the cDNA containing the RAMOSA3 open-reading frame.

SEQ ID NO:18 is the nucleotide sequence of the proteincoding region deduced from the PCR product obtained using the primers of SEQ ID NOs:16 & 17 to amplify maize cDNA.

SEQ ID NO:19 is the amino acid sequence of the RAMOSA3 polypeptide.

SEQ ID NO:20 is the nucleotide sequence of the 5' UTR-exon2 forward primer.

SEQ ID NO:21 is the nucleotide sequence of the 5' UTR-exon2 reverse primer.

SEQ ID NO:22 is the nucleotide sequence of the exon3exon4 forward primer.

SEQ ID NO:23 is the nucleotide sequence of the exon3-exon4 reverse primer.

SEQ ID NO:24 is the nucleotide sequence of the exon5-exon7 forward primer.

SEQ ID NO:25 is the nucleotide sequence of the exon5-exon7 reverse primer.

SEQ ID NO:26 is the nucleotide sequence of the exon8exon10 forward primer.

SEQ ID NO:27 is the nucleotide sequence of the exon8-exon10 reverse primer.

SEQ ID NO:28 is the nucleotide sequence of the exon11-3' UTR forward primer.

SEQ ID NO:29 is the nucleotide sequence of the exon11-3' UTR reverse primer.

SEQ ID NO:30 is the nucleotide sequence of a region in exon7 of the ra3-ref mutant gene, that contains a 4 base pair insertion relative to the sequence of SEQ ID NO:15.

SEQ ID NO:31 is the deduced amino acid sequence of the mutant ra3-ref RAMOSA3 polypeptide, which has a frameshift after amino acid 249, relative to SEQ ID NO:19, and a premature stop codon after 305 amino acids.

SEQ ID NO:32 is the nucleotide sequence of an ILS-1-like 5 transposon element present in the 5'-UTR region of the ra3-fea1 mutant gene.

SEQ ID NO:33 is the nucleotide sequence of a region of exon7 in the ra3-fea1 mutant gene, that contains a 4 base pair insertion relative to the sequence of SEQ ID NO:15.

SEQ ID NO:34 is the deduced amino acid sequence of the mutant ra3-fea1 RAMOSA3 polypeptide, which has a frameshift after amino acid 258 relative to SEQ ID NO:19, and a premature stop codon after 305 amino acids.

SEQ ID NO:35 is the nucleotide sequence of a region of 15 exon6 of the ra3-EV mutant gene, that contains a 4 base pair insertion relative to SEQ ID NO:15.

SEQ ID NO:36 is the deduced amino acid sequence of the mutant ra3-EV RAMOSA3 polypeptide, which has a frameshift after amino acid 224 relative to SEQ ID NO:19, and a 20 premature stop codon after 305 amino acids.

SEQ ID NO:37 is the nucleotide sequence of a region of exon10 of the ra3-NI mutant gene, that contains a 141 base pair insertion relative to SEQ ID NO:15.

SEQ ID NO:38 is the deduced amino acid sequence of the 25 mutant ra3-NI RAMOSA3 polypeptide, which has a different amino acid sequence after amino acid 333 relative to SEQ ID NO:19, and a premature stop codon after 335 amino acids.

SEQ ID NO:39 is the nucleotide sequence of a region between exon6 and exon7 of the ra3-bre mutant gene, that 30 contains a 10 base pair insertion relative to SEQ ID NO:15.

SEQ ID NO:40 is the deduced amino acid sequence of the mutant ra3-bre RAMOSA3 polypeptide, which has a frameshift after amino acid 241 and a premature stop codon after 243 amino acids.

SEQ ID NO:41 is the nucleotide sequence of region of exon6 of the ra3-JL mutant gene, that contains a deletion and rearrangement relative to SEQ ID NO:15.

SEQ ID NO:42: is the deduced amino acid sequence of the mutant ra3-JL RAMOSA3 polypeptide, which has a different 40 protein sequence after amino acid 217 and a premature stop codon after 246 amino acids.

SEQ ID NO:43 is the nucleotide sequence of a region of exon6 of the ra3-NS mutant gene, that contains a 2 base pair insertion relative to SEQ ID NO:15.

SEQ ID NO:44 is the deduced amino acid sequence of the mutant ra3-NS RAMOSA3 polypeptide, which has a frameshift after amino acid 222 and a premature stop codon after 299 amino acids.

SEQ ID NO:45 is the amino acid sequence of the conserved 50 "A-domain" phosphatase box, as described in Vogel et al. (*Plant J.* 13:673-683 (1998)) and in U.S. Patent Publication 2004-0229364-A1, the entire contents of which are herein incorporated by reference.

SEQ ID NO:46 is the amino acid sequence of the conserved 55 "B-domain" phosphatase box, as described in Vogel et al. (*Plant J.* 13:673-683 (1998)) and in U.S. Patent Publication 2004-0229364-A1.

SEQ ID NO:47 is the genomic nucleotide sequence containing the SISTER OF RAMOSA3 (SRA) gene.

SEQ ID NO:48 is the nucleotide sequence of the proteincoding region of the SRA gene.

SEQ ID NO:49 is the amino acid sequence of the SRA polypeptide.

SEQ ID NO:50 is a nucleotide sequence contained in the 65 clone my.cs1.pk0072.d4, which is a cDNA clone containing a fragment of the SRA gene.

14

SEQ ID NO:51 is the amino acid sequence of the rice trehalose-6-phosphate phosphatase polypeptide corresponding to NCBI GI NO. 33146623.

SEQ ID NO:52 is the amino acid sequence for the *Arabidopsis* AtTPPA polypeptide corresponding to NCBI GI NO. 2944178.

SEQ ID NO:53 is the amino acid sequence for the *Arabidopsis* AtTPPB polypeptide corresponding to NCBI GI NO. 2944180.

SEQ ID NO:54 is the amino acid sequence for a corn trehalose-6-phosphate phosphatase polypeptide that is cited as SEQ ID NO:16 in U.S. Patent Publication 2004-0229364-A1, the entire contents of which are herein incorporated by reference.

SEQ ID NO:55 is the amino acid sequence for a soybean trehalose-6-phosphate phosphatase polypeptide that is cited as SEQ ID NO:20 in U.S. Patent Publication 2004-0229364-A1

SEQ ID NO:56 is the nucleotide sequence of the NS487 primer.

SEQ ID NO:57 is the nucleotide sequence of the NS429 primer.

SEQ ID NO:58 is the nucleotide sequence of the NS483 primer.

SEQ ID NO:59 is the nucleotide sequence of the NS485 primer.

SEQ ID NO:60 is the nucleotide sequence of the NS488 primer.

SEQ ID NO:61 is the amino acid sequence of the Histagged RA3 protein produced in *E. coli*. SEQ ID NO:61 consists of a 37-aa N-terminal region that contains six consecutive histidine residues, followed by the 361-aa residues of the RA3 protein (SEQ ID NO:19).

SEQ ID NO:62 is the amino acid sequence of the Histagged RA3 TPP-domain fragment produced in *E. coli*. SEQ ID NO:62 consists of a 35-aa N-terminal region that contains six consecutive histidine residues, followed by amino acid residues 78-361 of the RA3 protein (SEQ ID NO:19).

SEQ ID NO:63 is the amino acid sequence of the Histagged RA3 N-terminal fragment produced in *E. coli*. SEQ ID NO:63 consists of a 34-aa N-terminal region that contains six consecutive histidine residues, followed by amino acid residues 1-78 of the RA3 protein (SEQ ID NO:19).

SEQ ID NO:64 is the nucleotide sequence of the NS489 primer.

SEQ ID NO:65 is the nucleotide sequence of the NS490 primer.

SEQ ID NO:66 is the nucleotide sequence of the NS500 primer.

SEQ ID NO:67 is the nucleotide sequence of the DNA fragment encoding a RA3 TPP-domain fragment, that was shown to rescue growth of the yeast tps2 mutant at the non-permissive temperature. SEQ ID NO:67 consists of an ATG start codon followed by nucleotides 235-1086 of SEQ ID NO:18.

SEQ ID NO:68 is the amino acid sequence of the RA3 TPP-domain fragment encoded by SEQ ID NO:67. SEQ ID NO:68 consists of a start methionine residue followed by amino acid residues 79-361 of SEQ ID NO:19.

SEQ ID NO:69 is the amino acid sequence of the SRA TPP-domain fragment, and corresponds to amino acids 76-370 of SEQ ID NO:49.

SEQ ID NO:70 corresponds to amino acids 92-385 of SEQ ID NO:52 (*Arabidopsis* AtTPPA); this polypeptide fragment has been shown to have enzymatic activity (Vogel et al. (1998) *Plant J* 13(5):673-683).

SEQ ID NO:71 corresponds to amino acids 92-374 of SEQ ID NO:53 (*Arabidopsis* AtTPPB).

The Sequence Listing contains the one letter code for nucleotide sequence characters and the three letter codes for amino acids as defined in conformity with the IUPAC- 5 IUBMB standards described in *Nucleic Acids Res.* 13:3021-3030 (1985) and in the *Biochemical J.* 219(2):345-373 (1984) which are herein incorporated by reference. The symbols and format used for nucleotide and amino acid sequence data comply with the rules set forth in 37 C.F.R. §1.822. The 10 sequence descriptions and Sequence Listing attached hereto comply with the rules governing nucleotide and/or amino acid sequence disclosures in patent applications as set forth in 37 C.F.R. §1.821-1.825.

### DETAILED DESCRIPTION OF THE INVENTION

The disclosure of each reference set forth herein is hereby incorporated by reference in its entirety.

As used herein and in the appended claims, the singular 20 forms "a", "an", and "the" include plural reference unless the context clearly dictates otherwise. Thus, for example, reference to "a plant" includes a plurality of such plants, reference to "a cell" includes one or more cells and equivalents thereof known to those skilled in the art, and so forth.

As Used Herein:

The term "RAMOSA3 (RA3) gene" is a gene of the present invention and refers to a non-heterologous form of a full-length RAMOSA3 (RA3) polynucleotide. In a preferred embodiment, the RAMOSA3 gene comprises SEQ ID NO:15 30 or 18.

"RAMOSA3 (RA3) polypeptide" refers to a polypeptide of the present invention and may comprise one or more amino acid sequences, in glycosylated or non-glycosylated form. In a preferred embodiment, the RAMOSA3 (RA3) polypeptide 35 comprises SEQ ID NO:19. A "RAMOSA3 (RA3) protein" comprises a RAMOSA3 (RA3) polypeptide.

"SISTER OF RAMOSA3 (SRA) gene" is a gene of the present invention and refers to a non-heterologous genomic form of a full-length SISTER OF RAMOSA3 (SRA) polynucleotide. In a preferred embodiment, the SISTER OF RAMOSA3 (SRA) gene comprises SEQ ID NO:47 or 48.

"SISTER OF RAMOSA3 (SRA) polypeptide" refers to a polypeptide of the present invention and may comprise one or more amino acid sequences, in glycosylated or non-glycosylated form. In a preferred embodiment, the SISTER OF RAMOSA3 (SRA) polypeptide comprises SEQ ID NO:49. A "SISTER OF RAMOSA3 (SRA) protein" comprises a SISTER OF RAMOSA3 (SRA) polypeptide.

"Transgenic" includes any cell, cell line, callus, tissue, 50 plant part or plant, the genome of which has been altered by the presence of a heterologous nucleic acid, such as a recombinant DNA construct, including those transgenics initially so altered as well as those created by sexual crosses or asexual propagation from the initial transgenic. The term "transgenic" as used herein does not encompass the alteration of the genome (chromosomal or extra-chromosomal) by conventional plant breeding methods or by naturally occurring events such as random cross-fertilization, non-recombinant viral infection, non-recombinant bacterial transformation, 60 non-recombinant transposition, or spontaneous mutation.

"Genome" as it applies to plant cells encompasses not only chromosomal DNA found within the nucleus, but organelle DNA found within subcellular components (e.g., mitochondrial, plastid) of the cell.

"Plant" includes reference to whole plants, plant organs, plant tissues, seeds and plant cells and progeny of same. Plant

16

cells include, without limitation, cells from seeds, suspension cultures, embryos, meristematic regions, callus tissue, leaves, roots, shoots, gametophytes, sporophytes, pollen, and microspores.

"Progeny" comprises any subsequent generation of a plant. "Transgenic plant" includes reference to a plant which comprises within its genome a heterologous polynucleotide. Preferably, the heterologous polynucleotide is stably integrated within the genome such that the polynucleotide is passed on to successive generations. The heterologous polynucleotide may be integrated into the genome alone or as part of a recombinant DNA construct.

"Heterologous" with respect to sequence means a sequence that originates from a foreign species, or, if from the same species, is substantially modified from its native form in composition and/or genomic locus by deliberate human intervention

"Polynucleotide", "nucleic acid sequence", "nucleotide sequence", or "nucleic acid fragment" are used interchangeably and is a polymer of RNA or DNA that is single or double-stranded, optionally containing synthetic, non-natural or altered nucleotide bases. Nucleotides (usually found in their 5'-monophosphate form) are referred to by their single letter designation as follows: "A" for adenylate or deoxyadenylate (for RNA or DNA, respectively), "C" for cytidylate or deoxycytidylate, "G" for guanylate or deoxyguanylate, "U" for uridylate, "T" for deoxythymidylate, "R" for purines (A or G), "Y" for pyrimidines (C or T), "K" for G or T, "H" for A or C or T, "I" for inosine, and "N" for any nucleotide.

"Polypeptide", "peptide", "amino acid sequence" and "protein" are used interchangeably herein to refer to a polymer of amino acid residues. The terms apply to amino acid polymers in which one or more amino acid residue is an artificial chemical analogue of a corresponding naturally occurring amino acid, as well as to naturally occurring amino acid polymers. The terms "polypeptide", "peptide", "amino acid sequence", and "protein" are also inclusive of modifications including, but not limited to, glycosylation, lipid attachment, sulfation, gamma-carboxylation of glutamic acid residues, hydroxylation and ADP-ribosylation.

"Messenger RNA (mRNA)" refers to the RNA that is without introns and that can be translated into protein by the cell.

"cDNA" refers to a DNA that is complementary to and synthesized from a mRNA template using the enzyme reverse transcriptase. The cDNA can be single-stranded or converted into the double-stranded form using the Klenow fragment of DNA polymerase I.

"Mature" protein refers to a post-translationally processed polypeptide; i.e., one from which any pre- or pro-peptides present in the primary translation product have been removed.

"Precursor" protein refers to the primary product of translation of mRNA; i.e., with pre- and pro-peptides still present. Pre- and pro-peptides may be and are not limited to intracellular localization signals.

"Isolated" refers to materials, such as nucleic acid molecules and/or proteins, which are substantially free or otherwise removed from components that normally accompany or interact with the materials in a naturally occurring environment. Isolated polynucleotides may be purified from a host cell in which they naturally occur. Conventional nucleic acid purification methods known to skilled artisans may be used to obtain isolated polynucleotides. The term also embraces recombinant polynucleotides and chemically synthesized polynucleotides.

"Recombinant" refers to an artificial combination of two otherwise separated segments of sequence, e.g., by chemical synthesis or by the manipulation of isolated segments of

nucleic acids by genetic engineering techniques. "Recombinant" also includes reference to a cell or vector, that has been modified by the introduction of a heterologous nucleic acid or a cell derived from a cell so modified, but does not encompass the alteration of the cell or vector by naturally occurring events (e.g., spontaneous mutation, natural transformation/transduction/transposition) such as those occurring without deliberate human intervention.

"Recombinant DNA construct" refers to a combination of nucleic acid fragments that are not normally found together in 10 nature. Accordingly, a recombinant DNA construct may comprise regulatory sequences and coding sequences that are derived from different sources, or regulatory sequences and coding sequences derived from the same source, but arranged in a manner different than that normally found in nature.

"Regulatory sequences" refer to nucleotide sequences located upstream (5' non-coding sequences), within, or downstream (3' non-coding sequences) of a coding sequence, and which influence the transcription, RNA processing or stability, or translation of the associated coding sequence. Regulatory sequences may include, but are not limited to, promoters, translation leader sequences, introns, and polyadenylation recognition sequences.

"Promoter" refers to a nucleic acid fragment capable of controlling transcription of another nucleic acid fragment.

"Promoter functional in a plant" is a promoter capable of controlling transcription in plant cells whether or not its origin is from a plant cell.

"Operably linked" refers to the association of nucleic acid fragments in a single fragment so that the function of one is 30 regulated by the other. For example, a promoter is operably linked with a nucleic acid fragment when it is capable of regulating the transcription of that nucleic acid fragment.

"Expression" refers to the production of a functional product. For example, expression of a nucleic acid fragment may 35 refer to transcription of the nucleic acid fragment (e.g., transcription resulting in mRNA or functional RNA) and/or translation of mRNA into a precursor or mature protein.

"Phenotype" means the detectable characteristics of a cell or organism.

"Introduced" in the context of inserting a nucleic acid fragment (e.g., a recombinant DNA construct) into a cell, means "transfection" or "transformation" or "transduction" and includes reference to the incorporation of a nucleic acid fragment into a eukaryotic or prokaryotic cell where the 45 nucleic acid fragment may be incorporated into the genome of the cell (e.g., chromosome, plasmid, plastid or mitochondrial DNA), converted into an autonomous replicon, or transiently expressed (e.g., transfected mRNA).

A "transformed cell" is any cell into which a nucleic acid 50 fragment (e.g., a recombinant DNA construct) has been introduced.

"Transformation" as used herein refers to both stable transformation and transient transformation.

"Stable transformation" refers to the introduction of a 55 nucleic acid fragment into a genome of a host organism resulting in genetically stable inheritance. Once stably transformed, the nucleic acid fragment is stably integrated in the genome of the host organism and any subsequent generation.

"Transient transformation" refers to the introduction of a 60 nucleic acid fragment into the nucleus, or DNA-containing organelle, of a host organism resulting in gene expression without genetically stable inheritance.

"Allele" is one of several alternative forms of a gene occupying a given locus on a chromosome. Different alleles of a 65 gene differ in their DNA sequence. When the alleles present at a given locus on a pair of homologous chromosomes in a

diploid plant are the same that plant is homozygous at that locus. If the alleles present at a given locus on a pair of homologous chromosomes in a diploid plant differ that plant is heterozygous at that locus. If a transgene is present on one of a pair of homologous chromosomes in a diploid plant that plant is hemizygous at that locus.

18

"Contig" refers to a nucleotide sequence that is assembled from two or more constituent nucleotide sequences that share common or overlapping regions of sequence homology. For example, the nucleotide sequences of two or more nucleic acid fragments can be compared and aligned in order to identify common or overlapping sequences. Where common or overlapping sequences exist between two or more nucleic acid fragments, the sequences (and thus their corresponding nucleic acid fragments) can be assembled into a single contiguous nucleotide sequence.

"Codon degeneracy" refers to divergence in the genetic code permitting variation of the nucleotide sequence without affecting the amino acid sequence of an encoded polypeptide. Accordingly, the instant invention relates to any nucleic acid fragment comprising a nucleotide sequence that encodes all or a substantial portion of the amino acid sequences set forth herein. The skilled artisan is well aware of the "codon-bias" exhibited by a specific host cell in usage of nucleotide codons to specify a given amino acid. Therefore, when synthesizing a nucleic acid fragment for improved expression in a host cell, it is desirable to design the nucleic acid fragment such that its frequency of codon usage approaches the frequency of preferred codon usage of the host cell.

"Synthetic nucleic acid fragments" can be assembled from oligonucleotide building blocks that are chemically synthesized using procedures known to those skilled in the art. These building blocks are ligated and annealed to form larger nucleic acid fragments which may then be enzymatically assembled to construct the entire desired nucleic acid fragment. "Chemically synthesized", as related to a nucleic acid fragment, means that the component nucleotides were assembled in vitro. Manual chemical synthesis of nucleic acid fragments may be accomplished using well-established pro-40 cedures, or automated chemical synthesis can be performed using one of a number of commercially available machines. Accordingly, the nucleic acid fragments can be tailored for optimal gene expression based on optimization of the nucleotide sequence to reflect the codon bias of the host cell. The skilled artisan appreciates the likelihood of successful gene expression if codon usage is biased towards those codons favored by the host. Determination of preferred codons can be based on a survey of genes derived from the host cell where sequence information is available.

The term "amplified" means the construction of multiple copies of a nucleic acid sequence or multiple copies complementary to the nucleic acid sequence using at least one of the nucleic acid sequences as a template. Amplification systems include the polymerase chain reaction (PCR) system, ligase chain reaction (LCR) system, nucleic acid sequence based amplification (NASBA, Cangene, Mississauga, Ontario), Q-Beta Replicase systems, transcription-based amplification system (TAS), and strand displacement amplification (SDA). See, e.g., Diagnostic Molecular Microbiology: Principles and Applications, D. H. Persing et al., Ed., American Society for Microbiology, Washington, D.C. (1993). The product of amplification is termed an amplicon.

The term "chromosomal location" includes reference to a length of a chromosome which may be measured by reference to the linear segment of DNA which it comprises. The chromosomal location can be defined by reference to two unique DNA sequences, i.e., markers.

The term "marker" includes reference to a locus on a chromosome that serves to identify a unique position on the chromosome. A "polymorphic marker" includes reference to a marker which appears in multiple forms (alleles) such that different forms of the marker, when they are present in a 5 homologous pair, allow transmission of each of the chromosomes in that pair to be followed. A genotype may be defined by use of one or a plurality of markers.

Sequence alignments and percent identity calculations may be determined using a variety of comparison methods designed to detect homologous sequences including, but not limited to, the Megalign program of the LASARGENE bioinformatics computing suite (DNASTAR Inc., Madison, Wis.). Unless stated otherwise, multiple alignment of the sequences provided herein were performed using the Clustal V method of alignment (Higgins and Sharp (1989) CABIOS. 5:151-153) with the default parameters (GAP PEN-ALTY=10, GAP LENGTH PENALTY=10). Default parameters for pairwise alignments and calculation of percent identity of protein sequences using the Clustal V method are 20 KTUPLE=1, GAP PENALTY=3, WINDOW=5 and DIAGO-NALS SAVED=5. For nucleic acids these parameters are KTUPLE=2, GAP PENALTY=5, WINDOW=4 and DIAGO-NALS SAVED=4. After alignment of the sequences, using the Clustal V program, it is possible to obtain "percent iden- 25 tity" and "divergence" values by viewing the "sequence distances" table on the same program; unless stated otherwise, percent identities and divergences provided and claimed herein were calculated in this manner.

Unless otherwise stated, "BLAST" sequence identity/ 30 similarity values provided herein refer to the value obtained using the BLAST 2.0 suite of programs using default parameters (Altschul et al., Nucleic Acids Res. 25:3389-3402 (1997)). Software for performing BLAST analyses is publicly available, e.g., through the National Center for Biotech- 35 nology Information. This algorithm involves first identifying high scoring sequence pairs (HSPs) by identifying short words of length W in the query sequence, which either match or satisfy some positive-valued threshold score T when aligned with a word of the same length in a database 40 sequence. T is referred to as the neighborhood word score threshold (Altschul et al., supra). These initial neighborhood word hits act as seeds for initiating searches to find longer HSPs containing them. The word hits are then extended in both directions along each sequence for as far as the cumu- 45 lative alignment score can be increased. Cumulative scores are calculated using, for nucleotide sequences, the parameters M (reward score for a pair of matching residues; always >0) and N (penalty score for mismatching residues; always <0). For amino acid sequences, a scoring matrix is used to calcu- 50 late the cumulative score. Extension of the word hits in each direction are halted when: the cumulative alignment score falls off by the quantity X from its maximum achieved value; the cumulative score goes to zero or below, due to the accumulation of one or more negative-scoring residue alignments; 55 or the end of either sequence is reached. The BLAST algorithm parameters W, T, and X determine the sensitivity and speed of the alignment. The BLASTN program (for nucleotide sequences) uses as defaults a wordlength (W) of 11, an expectation (E) of 10, a cutoff of 100, M=5, N=-4, and a 60 comparison of both strands. For amino acid sequences, the BLASTP program uses as defaults a wordlength (W) of 3, an expectation (E) of 10, and the BLOSUM62 scoring matrix (see Henikoff & Henikoff, Proc. Natl. Acad. Sci. USA 89:10915 (1989)).

Standard recombinant DNA and molecular cloning techniques used herein are well known in the art and are described

20

more fully in Sambrook, J., Fritsch, E. F. and Maniatis, T. *Molecular Cloning: A Laboratory Manual*; Cold Spring Harbor Laboratory Press: Cold Spring Harbor, 1989 (hereinafter "Sambrook").

Turning now to preferred embodiments:

The present invention includes isolated polynucleotides.

In one preferred embodiment, an isolated polynucleotide comprises: (a) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant transformed with said isolated polynucleotide results in alteration of the branching of the tassel, ear, or both, of said transformed plant when compared to a control plant not comprising said isolated polynucleotide; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, expression of said polypeptide results in a decrease in the branching of the tassel, ear, or both, and even more preferably, the plant is maize.

In another preferred embodiment, an isolated polynucleotide comprises: (a) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant transformed with said isolated polynucleotide results in alteration of pollen shed of said transformed plant when compared to a control plant not comprising said isolated polynucleotide; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, expression of said polypeptide results in a decrease in pollen shed, and even more preferably, the plant is maize.

In another preferred embodiment, an isolated polynucleotide comprises: (a) a nucleotide sequence encoding a polypeptide associated with branching of the tassel, ear, or both, of a plant (preferably maize), wherein said polypeptide has an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary.

In another preferred embodiment, an isolated polynucleotide comprises: (a) a nucleotide sequence encoding a polypeptide associated with pollen shed of a plant (preferably maize), wherein said polypeptide has an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary.

A polypeptide is "associated with branching" or "associated with pollen shed" in that the absence of the polypeptide in a plant results in an increase in branching or pollen shed of the plant when compared to a plant that expresses the polypeptide.

In another preferred embodiment, an isolated polynucleotide comprises: (a) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence

identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant exhibiting a ramosa3 mutant phenotype results in an decrease of branching of the tassel, ear, or both of the plant; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, the plant is maize.

In another preferred embodiment, an isolated polynucle-otide comprises: (a) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant exhibiting a ramosa3 mutant phenotype results in an decrease of pollen shed of the plant; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, the 20 plant is maize.

In another preferred embodiment, an isolated polynucle-otide comprises: (a) a nucleic acid sequence encoding a polypeptide having trehalose-6-phosphate phosphatase activity, wherein the polypeptide has an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69; or (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary. Preferably, when compared to SEQ ID NO:68 or 69, the polypeptide has an amino acid sequence of at least 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of align-35 ment.

The present invention also includes isolated polypeptides. In a preferred embodiment, an isolated polypeptide comprises an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based 40 on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant transformed with an isolated polynucleotide encoding said polypeptide results in alteration of the branching of the tassel, ear, or both, of the plant, when compared to a control 45 plant not comprising said expressed polypeptide. Preferably, expression of said polypeptide results in a decrease in the branching, and even more preferably, the plant is maize.

In another preferred embodiment, an isolated polypeptide comprises an amino acid sequence of at least 80%, 85%, 90%, 50 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant transformed with an isolated polynucleotide encoding said polypeptide results in alteration of pollen shed of the 55 plant, when compared to a control plant not comprising said expressed polypeptide. Preferably, expression of said polypeptide results in a decrease in the pollen shed, and even more preferably, the plant is maize.

In another preferred embodiment, an isolated polypeptide 60 comprises an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant exhibiting a ramosa3 mutant phenotype results in an 65 decrease of branching of the tassel, ear, or both, of the plant. Preferably, the plant is maize.

22

In another preferred embodiment, an isolated polypeptide comprises an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein expression of said polypeptide in a plant exhibiting a ramosa3 mutant phenotype results in an decrease of pollen shed of the plant. Preferably, the plant is maize.

Another preferred embodiment included within the present invention is an isolated polypeptide associated with branching of the tassel, ear, or both, of a plant (preferably maize), wherein said polypeptide has an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19.

Another preferred embodiment is an isolated polypeptide associated with pollen shed of a plant (preferably maize), wherein said polypeptide has an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19.

Still another preferred embodiment is an isolated polypeptide having trehalose-6-phosphate phosphatase activity, wherein the polypeptide has an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69.

It is understood, as those skilled in the art will appreciate, that the invention encompasses more than the specific exemplary sequences. Alterations in a nucleic acid fragment which result in the production of a chemically equivalent amino acid at a given site, but do not effect the functional properties of the encoded polypeptide, are well known in the art. For example, a codon for the amino acid alanine, a hydrophobic amino acid, may be substituted by a codon encoding another less hydrophobic residue, such as glycine, or a more hydrophobic residue, such as valine, leucine, or isoleucine. Similarly, changes which result in substitution of one negatively charged residue for another, such as aspartic acid for glutamic acid, or one positively charged residue for another, such as lysine for arginine, can also be expected to produce a functionally equivalent product. Nucleotide changes which result in alteration of the N-terminal and C-terminal portions of the polypeptide molecule would also not be expected to alter the activity of the polypeptide. Each of the proposed modifications is well within the routine skill in the art, as is determination of retention of biological activity of the encoded products.

The present invention also includes a recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in said plant, wherein said polynucleotide comprises an isolated polynucleotide of the present invention, such as a preferred polynucleotide as described above.

In one preferred embodiment, a recombinant DNA construct comprises a polynucleotide operably linked to a promoter that is functional in said plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69. Preferably, when compared to SEQ ID NO:68 or 69, the polypeptide has an amino acid sequence of at least 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment.

In another preferred embodiment, a recombinant DNA construct comprises a polynucleotide operably linked to a promoter that is functional in said plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19.

The present invention also includes a suppression DNA construct

A suppression construct preferably comprises a promoter functional in a plant operably linked to (a) all or part of (i) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 50% sequence identity, or any integer up to and including 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69, or (ii) a full complement of the nucleic acid sequence of (a)(i); (b) a region derived from all or part of a sense strand or antisense strand of a target gene of interest, said region having a nucleic acid sequence of at least 20 50% sequence identity, based on the Clustal V method of alignment, when compared to said all or part of a sense strand or antisense strand from which said region is derived, and wherein said target gene of interest encodes a RAMOSA3 (RA3) polypeptide or a SISTER OF RAMOSA3 (SRA) 25 polypeptide; or (c) a nucleic acid sequence of at least 50% sequence identity, or any integer up to and including 100% identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:15, 18, 47, 48 or 67. The suppression DNA construct preferably comprises a cosuppression 30 construct, antisense construct, viral-suppression construct, hairpin suppression construct, stem-loop suppression construct, double-stranded RNA-producing construct, RNAi construct, or small RNA construct (e.g., an sRNA construct or an miRNA construct).

As used herein, "suppression DNA construct" is a recombinant DNA construct which when transformed or stably integrated into the genome of the plant, results in "silencing" of a target gene in the plant. The target gene may be endogenous or transgenic to the plant. "Silencing," as used herein with respect to the target gene, refers generally to the suppression of levels of mRNA or protein/enzyme expressed by the target gene, and/or the level of the enzyme activity or protein functionality. The term "suppression" includes lower, reduce, decline, decrease, inhibit, eliminate and prevent. "Silencing" or "gene silencing" does not specify mechanism and is inclusive, and not limited to, anti-sense, cosuppression, viral-suppression, hairpin suppression, stem-loop suppression, RNAi-based approaches, and small RNA-based approaches.

A suppression DNA construct may comprise a region derived from a target gene of interest and may comprise all or part of the nucleic acid sequence of the sense strand (or antisense strand) of the target gene of interest. Depending upon the approach to be utilized, the region may be 100% 55 identical or less than 100% identical (e.g., at least 50% or any integer between 50% and 100% identical) to all or part of the sense strand (or antisense strand) of the gene of interest.

Suppression DNA constructs are well-known in the art, are readily constructed once the target gene of interest is selected, 60 and include, without limitation, cosuppression constructs, antisense constructs, viral-suppression constructs, hairpin suppression constructs, stem-loop suppression constructs, double-stranded RNA-producing constructs, and more generally, RNAi (RNA interference) constructs and small RNA 65 constructs such as sRNA (short interfering RNA) constructs and miRNA (microRNA) constructs.

24

"Antisense inhibition" refers to the production of antisense RNA transcripts capable of suppressing the expression of the target protein.

"Antisense RNA" refers to an RNA transcript that is complementary to all or part of a target primary transcript or mRNA and that blocks the expression of a target isolated nucleic acid fragment (U.S. Pat. No. 5,107,065). The complementarity of an antisense RNA may be with any part of the specific gene transcript, i.e., at the 5' non-coding sequence, 3' non-coding sequence, introns, or the coding sequence.

"Cosuppression" refers to the production of sense RNA transcripts capable of suppressing the expression of the target protein. "Sense" RNA refers to RNA transcript that includes the mRNA and can be translated into protein within a cell or in vitro. Cosuppression constructs in plants have been previously designed by focusing on overexpression of a nucleic acid sequence having homology to a native mRNA, in the sense orientation, which results in the reduction of all RNA having homology to the overexpressed sequence (see Vaucheret et al. (1998) *Plant J.* 16:651-659; and Gura (2000) *Nature* 404:804-808).

A number of promoters can be used in recombinant DNA constructs and suppression DNA constructs of the present invention. The promoters can be selected based on the desired outcome, and may include constitutive, tissue-specific, inducible, or other promoters for expression in the host organism.

High level, constitutive expression of the candidate gene under control of the 35S promoter may have pleiotropic affects. However, tissue specific and/or stress-specific expression may eliminate undesirable affects but retain the ability to enhance drought tolerance. This affect has been observed in *Arabidopsis* (Kasuga et al. (1999) Nature Biotechnol. 17:287-91). As such, candidate gene efficacy may be tested when driven by different promoters.

Suitable constitutive promoters for use in a plant host cell include, for example, the core promoter of the Rsyn7 promoter and other constitutive promoters disclosed in WO 99/43838 and U.S. Pat. No. 6,072,050; the core CaMV 35S promoter (Odell et al., Nature 313:810-812 (1985)); rice actin (McElroy et al., Plant Cell 2:163-171 (1990)); ubiquitin (Christensen et al., Plant Mol. Biol. 12:619-632 (1989) and Christensen et al., Plant Mol. Biol. 18:675-689 (1992)); pEMU (Last et al., Theor. Appl. Genet. 81:581-588 (1991)); MAS (Velten et al., EMBO J. 3:2723-2730 (1984)); ALS promoter (U.S. Pat. No. 5,659,026), and the like. Other constitutive promoters include, for example, those discussed in U.S. Pat. Nos. 5,608,149; 5,608,144; 5,604,121; 5,569,597; 5,466,785; 5,399,680; 5,268,463; 5,608,142; and 6,177,611.

In choosing a promoter to use in the methods of the invention, it may be desirable to use a tissue-specific or developmentally regulated promoter. A preferred tissue-specific or developmentally regulated promoter is a DNA sequence which regulates the expression of a DNA sequence selectively in the cells/tissues of a plant critical to tassel development, seed set, or both, and limits the expression of such a DNA sequence to the period of tassel development or seed maturation in the plant. Any identifiable promoter may be used in the methods of the present invention which causes the desired temporal and spatial expression.

Promoters which are seed or embryo specific and may be useful in the invention include soybean Kunitz trysin inhibitor (Kti3, Jofuku and Goldberg, Plant Cell 1:1079-1093 (1989)), patatin (potato tubers) (Rocha-Sosa, M., et al. (1989) EMBO J. 8:23-29), convicilin, vicilin, and legumin (pea cotyledons) (Rerie, W. G., et al. (1991) Mol. Gen. Genet. 259: 149-157; Newbigin, E. J., et al. (1990) Planta 180:461-470;

Higgins, T. J. V., et al. (1988) Plant. Mol. Biol. 11:683-695), zein (maize endosperm) (Schemthaner, J. P., et al. (1988) EMBO J. 7:1249-1255), phaseolin (bean cotyledon) (Segupta-Gopalan, C., et al. (1985) Proc. Natl. Acad. Sci. U.S.A. 82:3320-3324), phytohemagglutinin (bean cotyledon) (Voelker, T. et al. (1987) EMBO J. 6:3571-3577), B-conglycinin and glycinin (sovbean cotyledon) (Chen, Z-L, et al. (1988) EMBO J. 7:297-302), glutelin (rice endosperm), hordein (barley endosperm) (Marris, C., et al. (1988) Plant Mol. Biol. 10:359-366), glutenin and gliadin (wheat endosperm) (Colot, V., et al. (1987) EMBO J. 6:3559-3564), and sporamin (sweet potato tuberous root) (Hattori, T., et al. (1990) Plant Mol. Biol. 14:595-604). Promoters of seed-specific genes operably linked to heterologous coding regions in chimeric 15 gene constructions maintain their temporal and spatial expression pattern in transgenic plants. Such examples include Arabidopsis thaliana 2S seed storage protein gene promoter to express enkephalin peptides in Arabidopsis and Brassica napus seeds (Vanderkerckhove et al., Bio/Technol- 20 ogy 7:L929-932 (1989)), bean lectin and bean beta-phaseolin promoters to express luciferase (Riggs et al., Plant Sci. 63:47-57 (1989)), and wheat glutenin promoters to express chloramphenicol acetyl transferase (Colot et al., EMBO J. 6:3559-3564 (1987)).

Inducible promoters selectively express an operably linked DNA sequence in response to the presence of an endogenous or exogenous stimulus, for example by chemical compounds (chemical inducers) or in response to environmental, hormonal, chemical, and/or developmental signals. Inducible or regulated promoters include, for example, promoters regulated by light, heat, stress, flooding or drought, phytohormones, wounding, or chemicals such as ethanol, jasmonate, salicylic acid, or safeners.

Promoters which are timed to stress include the following: 1) the RD29A promoter (Kasuga et al. (1999) Nature Biotechnol. 17:287-91); 2) barley promoter, B22E; expression of B22E is specific to the pedicel in developing maize kernels ("Primary Structure of a Novel Barley Gene Differentially 40 Expressed in Immature Aleurone Layers". Klemsdae, S. S. et al., Mol. Gen. Genet. 228(1/2):9-16 (1991)); and 3) maize promoter, Zag2 ("Identification and molecular characterization of ZAG1, the maize homolog of the Arabidopsis floral homeotic gene AGAMOUS", Schmidt, R. J. et al., Plant Cell 45 5(7):729-737 (1993)). Zag2 transcripts can be detected 5 days prior to pollination to 7 to 8 DAP, and directs expression in the carpel of developing female inflorescences and Ciml which is specific to the nucleus of developing maize kernels. Ciml transcript is detected 4 to 5 days before pollination to 6 to 8 50 DAP. Other useful promoters include any promoter which can be derived from a gene whose expression is maternally associated with developing female florets.

Promoters may be derived in their entirety from a native gene, or be composed of different elements derived from 55 different promoters found in nature, or even comprise synthetic DNA segments. It is understood by those skilled in the art that different promoters may direct the expression of a gene in different tissues or cell types, or at different stages of development, or in response to different environmental conditions. It is further recognized that since in most cases the exact boundaries of regulatory sequences have not been completely defined, DNA fragments of some variation may have identical promoter activity. Promoters that cause a gene to be expressed in most cell types at most times are commonly 65 referred to as "constitutive promoters". New promoters of various types useful in plant cells are constantly being dis-

26

covered; numerous examples may be found in the compilation by Okamuro, J. K., and Goldberg, R. B., Biochemistry of Plants 15:1-82 (1989).

Particularly preferred promoters may include: RIP2, mLIP15, ZmCOR1, Rab17, CaMV 35S, RD29A, SAM synthetase, ubiquitin, CaMV 19S, nos, Adh, sucrose synthase, R-allele, or root cell promoter.

Recombinant DNA constructs and suppression DNA constructs of the present invention may also include other regulatory sequences, including but not limited to, translation leader sequences, introns, and polyadenylation recognition sequences. In another preferred embodiment of the present invention, a recombinant DNA construct of the present invention further comprises an enhancer or silencer.

15 An intron sequence can be added to the 5' untranslated region or the coding sequence of the partial coding sequence to increase the amount of the mature message that accumulates in the cytosol. Inclusion of a spliceable intron in the transcription unit in both plant and animal expression constructs has been shown to increase gene expression at both the mRNA and protein levels up to 1000-fold. Buchman and Berg, *Mol. Cell. Biol.* 8:4395-4405 (1988); Callis et al., *Genes Dev.* 1:1183-1200 (1987). Such intron enhancement of gene expression is typically greatest when placed near the 5' end of the transcription unit. Use of maize introns Adh1-S intron 1, 2, and 6, the Bronze-1 intron are known in the art. See generally, *The Maize Handbook, Chapter* 116, Freeling and Walbot, Eds., Springer, N.Y. (1994).

If polypeptide expression is desired, it is generally desirable to include a polyadenylation region at the 3'-end of a polynucleotide coding region. The polyadenylation region can be derived from the natural gene, from a variety of other plant genes, or from T-DNA. The 3' end sequence to be added can be derived from, for example, the nopaline synthase or octopine synthase genes, or alternatively from another plant gene, or less preferably from any other eukaryotic gene.

A translation leader sequence is a DNA sequence located between the promoter sequence of a gene and the coding sequence. The translation leader sequence is present in the fully processed mRNA upstream of the translation start sequence. The translation leader sequence may affect processing of the primary transcript to mRNA, mRNA stability or translation efficiency. Examples of translation leader sequences have been described (Turner, R. and Foster, G. D. (1995) Molecular Biotechnology 3:225).

Any plant can be selected for the identification of regulatory sequences and genes to be used in creating recombinant DNA constructs and suppression DNA constructs of the present invention. Examples of suitable plant targets for the isolation of genes and regulatory sequences would include but are not limited to alfalfa, apple, apricot, Arabidopsis, artichoke, arugula, asparagus, avocado, banana, barley, beans, beet, blackberry, blueberry, broccoli, brussels sprouts, cabbage, canola, cantaloupe, carrot, cassaya, castorbean, cauliflower, celery, cherry, chicory, cilantro, citrus, clementines, clover, coconut, coffee, corn, cotton, cranberry, cucumber, Douglas fir, eggplant, endive, escarole, eucalyptus, fennel, figs, garlic, gourd, grape, grapefruit, honey dew, jicama, kiwifruit, lettuce, leeks, lemon, lime, Loblolly pine, linseed, mango, melon, mushroom, nectarine, nut, oat, oil palm, oil seed rape, okra, olive, onion, orange, an ornamental plant, palm, papaya, parsley, parsnip, pea, peach, peanut, pear, pepper, persimmon, pine, pineapple, plantain, plum, pomegranate, poplar, potato, pumpkin, quince, radiata pine, radiscchio, radish, rapeseed, raspberry, rice, rye, sorghum, Southern pine, soybean, spinach, squash, strawberry, sugarbeet, sugarcane, sunflower, sweet potato, sweetgum, tangerine, tea,

tobacco, tomato, triticale, turf, turnip, a vine, watermelon, wheat, yams, and zucchini. Particularly preferred plants for the identification of regulatory sequences are Arabidopsis, corn, wheat, soybean, and cotton.

The present invention also includes a plant comprising in 5 its genome a recombinant DNA construct of the present invention (such as a preferred construct discussed above). Preferably, the recombinant DNA construct is stably integrated into the genome of the plant.

The present invention also includes a plant whose genome 10 comprises a disruption (e.g., an insertion, such as a transposable element, or sequence mutation) of at least one gene (which may be heterologous or endogenous to the genome) encoding a polypeptide selected from the group consisting of a RAMOSA3 (RA3) polypeptide or a SISTER OF 15 tional in a plant operably linked to: RAMOSA3 (SRA) polypeptide.

Also included in the present invention are any progeny of a plant of the present invention, and any seed obtained from such a plant or its progeny. Progeny includes subsequent generations obtained by self-pollination or out-crossing of a 20 plant. Progeny also includes hybrids and inbreds. Preferably, in hybrid seed propagated crops, mature transgenic plants can be self-crossed to produce a homozygous inbred plant. The inbred plant produces seed containing the newly introduced recombinant DNA construct. These seeds can be grown to 25 produce plants that would exhibit increased drought tolerance, or used in a breeding program to produce hybrid seed, which can be grown to produce plants that would exhibit increased drought tolerance. Preferably, the seeds are maize.

Preferably, a plant of the present invention is a monocotyledonous or dicotyledonous plant, more preferably, a maize or soybean plant, even more preferably a maize plant, such as a maize hybrid plant or a maize inbred plant. The plant may also be sunflower, sorghum, canola, wheat, alfalfa, cotton, rice, barley or millet.

Particularly preferred embodiments of plants of the present invention include:

- 1. A plant (preferably maize or soybean, more preferably a plant exhibiting a ramosa3 mutant phenotype) comprising in its genome a recombinant DNA construct comprising an iso-40 lated polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein said plant exhibits alteration (preferably a decrease) of branching of the 45 tassel, ear, or both, of said plant when compared to a control plant not comprising said recombinant DNA construct.
- 2. A plant (preferably maize or soybean, more preferably a plant exhibiting a ramosa3 mutant phenotype) comprising in its genome a recombinant DNA construct comprising an iso- 50 lated polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, wherein said plant exhibits alteration (preferably a decrease) of pollen shed of 55 said plant when compared to a control plant not comprising said recombinant DNA construct.
- A plant (preferably maize or soybean, more preferably a plant exhibiting a ramosa3 mutant phenotype) comprising in its genome a recombinant DNA construct comprising an iso- 60 lated polypeptide having an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69, wherein said plant exhibits increased trehalose-6- 65 phosphate phosphatase activity when compared to a control plant not comprising said recombinant DNA construct.

28

- 4. A plant (preferably maize or soybean, more preferably a plant exhibiting a ramosa3 mutant phenotype) comprising in its genome a recombinant DNA construct comprising an isolated polypeptide having an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69, wherein said plant exhibits increased environmental stress tolerance (preferably drought tolerance) when compared to a control plant not comprising said recombinant DNA construct.
- 5. A plant (preferably maize or soybean) comprising in its genome:
- a suppression DNA construct comprising a promoter func-
  - (a) all or part of (i) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 50% sequence identity, or any integer up to and including 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69, or (ii) a full complement of the nucleic acid sequence of (a)(i); or
  - (b) a region derived from all or part of a sense strand or antisense strand of a target gene of interest, said region having a nucleic acid sequence of at least 50% sequence identity, based on the Clustal V method of alignment, when compared to said all or part of a sense strand or antisense strand from which said region is derived, and wherein said target gene of interest encodes a polypeptide selected from the group consisting of a RAMOSA3 (RA3) polypeptide or a SISTER OF RAMOSA3 (SRA) polypeptide,

and wherein said plant exhibits increased branching of the tassel, ear, or both, and/or increased pollen shed, and/or 35 reduced trehalose-6-phosphate phosphatase activity when compared to a control plant not comprising said suppression DNA construct. The suppression DNA construct preferably comprises a cosuppression construct, antisense construct, viral-suppression construct, hairpin suppression construct, stem-loop suppression construct, double-stranded RNA-producing construct, RNAi construct, or small RNA construct (e.g., an sRNA construct or an miRNA construct).

- 6. A plant (preferably maize or soybean) whose genome comprises a disruption (e.g., an insertion, such as a transposable element, or sequence mutation) of at least one gene (which may be heterologous or endogenous to the genome) encoding a polypeptide selected from the group consisting of a RAMOSA3 (RA3) polypeptide or a SISTER OF RAMOSA3 (SRA) polypeptide, wherein said disruption results in said plant exhibiting increased branching of the tassel, ear, or both, and/or increased pollen shed, and/or reduced trehalose-6-phosphate phosphatase activity when compared to a control plant not comprising said disruption. Preferably, relative to SEQ ID NO:15, the disruption comprises any one of the insertions shown in SEQ ID NOs:30, 32, 33, 35, 37, 39 or 43, or the deletion and rearrangement shown in SEQ ID NO:41.
- 7. Any progeny of the above plants 1-6, any seeds of the above plants 1-6, any seeds of progeny of the above plants 1-6, and cells from any of the above plants 1-6 and progeny.

The present invention also includes methods for altering branching of the tassel, ear, or both, of a plant; methods for altering pollen shed of a plant; methods for altering trehalose-6-phosphate phosphatase activity in a plant; and methods for increasing environmental stress tolerance (preferably drought tolerance) in a plant. Preferably, the plant is a monocotyledonous or dicotyledonous plant, more preferably, a

maize or soybean plant, even more preferably a maize plant. The plant may also be sunflower, sorghum, canola, wheat, alfalfa, cotton, rice, barley or millet.

In one preferred embodiment, a method for altering branching of the tassel, ear, or both, of a plant, comprises: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce transformed plant cells, said recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in a plant, wherein said polynucleotide encodes a polypeptide having an amino acid 10 sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19; and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its 15 genome said recombinant DNA construct and wherein said transgenic plant exhibits an alteration in branching of the tassel, ear, or both, when compared to a control plant not comprising said recombinant DNA construct. The method may further comprise (c) obtaining a progeny plant derived 20 from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct. Preferably, the transgenic plant or progeny thereof exhibits a decrease in branching of the tassel, ear, or both.

In another preferred embodiment, a method for altering 25 pollen shed of a plant, comprises: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce transformed plant cells, said recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in a plant, wherein said polynucleotide 30 encodes a polypeptide having an amino acid sequence of at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19; and (b) regenerating a transgenic plant from said transformed plant cell, 35 wherein said transgenic plant comprises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an alteration in pollen shed, when compared to a control plant not comprising said recombinant DNA construct. The method may further comprise (c) obtaining a 40 progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct. Preferably, the transgenic plant or progeny thereof exhibits a decrease in pollen shed.

Another preferred method of the present invention is a 45 method for altering trehalose-6-phosphate phosphatase activity in a plant, comprising: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce transformed plant cells, said recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is 50 functional in a plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69; 55 and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an alteration in trehalose-6-phosphate phosphatase activity, when compared to a control plant 60 not comprising said recombinant DNA construct. The method may further comprise (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct. Preferably, the transgenic plant or progeny thereof exhibits an increase in trehalose-6-phosphate phosphatase activity.

30

In another preferred embodiment, a method for increasing environmental stress tolerance (preferably drought tolerance) of a plant, comprises: (a) introducing into a regenerable plant cell a recombinant DNA construct to produce transformed plant cells, said recombinant DNA construct comprising a polynucleotide operably linked to a promoter that is functional in a plant, wherein said polynucleotide encodes a polypeptide having an amino acid sequence of at least 65%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99% or 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69; and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an increase in environmental stress tolerance (preferably drought tolerance), when compared to a control plant not comprising said recombinant DNA construct. The method may further comprise (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct.

In yet another preferred embodiment, a method for increasing branching of the tassel, ear, or both, and/or increasing pollen shed, and/or reducing trehalose-6-phosphate phosphatase activity a plant, comprises: (a) introducing into a regenerable plant cell a suppression DNA construct to produce transformed plant cells, said suppression DNA construct comprising a promoter functional in a plant operably linked to (i) all or part of (A) a nucleic acid sequence encoding a polypeptide having an amino acid sequence of at least 50% sequence identity, or any integer up to and including 100% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69, or (B) a full complement of the nucleic acid sequence of (i)(A), or (ii) a region derived from all or part of a sense strand or antisense strand of a target gene of interest, said region having a nucleic acid sequence of at least 50% sequence identity, based on the Clustal V method of alignment, when compared to said all or part of a sense strand or antisense strand from which said region is derived, and wherein said target gene of interest encodes a polypeptide selected from the group consisting of a RAMOSA3 (RA3) polypeptide or a SISTER OF RAMOSA3 (SRA) polypeptide; and (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said suppression DNA construct and wherein said transgenic plant exhibits increased branching of the tassel, ear, or both, and/or increased pollen shed, and/or reduced trehalose-6-phosphate phosphatase activity when compared to a control plant not comprising said suppression DNA construct. The method may further comprise (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the suppression DNA construct.

The introduction of recombinant DNA constructs of the present invention into plants may be carried out by any suitable technique, including but not limited to direct DNA uptake, chemical treatment, electroporation, microinjection, cell fusion, infection, vector mediated DNA transfer, bombardment, or *Agrobacterium* mediated transformation.

Preferred techniques are set forth below in Example 6 for transformation of maize plant cells and in Example 7 for transformation of soybean plant cells.

Other preferred methods for transforming dicots, primarily by use of *Agrobacterium tumefaciens*, and obtaining transgenic plants include those published for cotton (U.S. Pat. Nos. 5,004,863, 5,159,135, 5,518,908); soybean (U.S. Pat. Nos. 5,569,834, 5,416,011, McCabe et. al., Bio/Technology 6:923

(1988), Christou et al., Plant Physiol. 87:671 674 (1988)); *Brassica* (U.S. Pat. No. 5,463,174); peanut (Cheng et al., Plant Cell Rep. 15:653 657 (1996), McKently et al., Plant Cell Rep. 14:699 703 (1995)); papaya; and pea (Grant et al., Plant Cell Rep. 15:254 258, (1995)).

Transformation of monocotyledons using electroporation, particle bombardment, and Agrobacterium have also been reported and are included as preferred methods, for example, transformation and plant regeneration as achieved in asparagus (Bytebier et al., Proc. Natl. Acad. Sci. (USA) 84:5354, 10 (1987)); barley (Wan and Lemaux, Plant Physiol 104:37 (1994)); Zea mays (Rhodes et al., Science 240:204 (1988), Gordon-Kamm et al., Plant Cell 2:603 618 (1990), Fromm et al., Bio/Technology 8:833 (1990), Koziel et al., Bio/Technology 11: 194, (1993), Armstrong et al., Crop Science 35:550 15 557 (1995)); oat (Somers et al., Bio/Technology 10: 15 89 (1992)); orchard grass (Horn et al., Plant Cell Rep. 7:469 (1988)); rice (Toriyama et al., TheorAppl. Genet. 205:34, (1986); Part et al., Plant Mol. Biol. 32:1135 1148, (1996); Abedinia et al., Aust. J. Plant Physiol. 24:133 141 (1997); 20 Zhang and Wu, Theor. Appl. Genet. 76:835 (1988); Zhang et al. Plant Cell Rep. 7:379, (1988); Battraw and Hall, Plant Sci. 86:191 202 (1992); Christou et al., Bio/Technology 9:957 (1991)); rye (De la Pena et al., Nature 325:274 (1987)); sugarcane (Bower and Birch, Plant J. 2:409 (1992)); tall fescue 25 (Wang et al., Bio/Technology 10:691 (1992)), and wheat (Vasil et al., Bio/Technology 10:667 (1992); U.S. Pat. No. 5.631.152).

There are a variety of methods for the regeneration of plants from plant tissue. The particular method of regeneration will depend on the starting plant tissue and the particular plant species to be regenerated.

The regeneration, development, and cultivation of plants from single plant protoplast transformants or from various transformed explants is well known in the art (Weissbach and 35 Weissbach, In: Methods for Plant Molecular Biology, (Eds.), Academic Press, Inc. San Diego, Calif., (1988)). This regeneration and growth process typically includes the steps of selection of transformed cells, culturing those individualized cells through the usual stages of embryonic development 40 through the rooted plantlet stage. Transgenic embryos and seeds are similarly regenerated. The resulting transgenic rooted shoots are thereafter planted in an appropriate plant growth medium such as soil.

The development or regeneration of plants containing the 45 foreign, exogenous isolated nucleic acid fragment that encodes a protein of interest is well known in the art. Preferably, the regenerated plants are self-pollinated to provide homozygous transgenic plants. Otherwise, pollen obtained from the regenerated plants is crossed to seed-grown plants of 50 agronomically important lines. Conversely, pollen from plants of these important lines is used to pollinate regenerated plants. A transgenic plant of the present invention containing a desired polypeptide is cultivated using methods well known to one skilled in the art.

Assays to detect proteins may be performed by SDS-polyacrylamide gel electrophoresis or immunological assays. Assays to detect levels of substrates or products of enzymes may be performed using gas chromatography or liquid chromatography for separation and UV or visible spectrometry or mass spectrometry for detection, or the like. Determining the levels of mRNA of the enzyme of interest may be accomplished using northern-blotting or RT-PCR techniques. Once plants have been regenerated, and progeny plants homozygous for the transgene have been obtained, plants will have a stable phenotype that will be observed in similar seeds in later generations.

32

The present invention also includes a method for determining whether a plant exhibits a ramosa3 mutant genotype comprising: (a) isolating genomic DNA from a subject; (b) performing a PCR on the isolated genomic DNA using the primer pair consisting of NS432 (SEQ ID NO:16) and NS411 (SEQ ID NO:17); and (c) analyzing results of the PCR for the presence of a larger DNA fragment as an indication that the subject exhibits the ramosa3 mutant genotype.

Also included in the present invention is a method for determining whether a plant exhibits a ramosa3 mutant genotype comprising: (a) isolating genomic DNA from a subject; (b) performing a PCR on the isolated genomic DNA using any one of the following primer pairs: SEQ ID NOs:16 and 17; SEQ ID NOs:20 and 21; SEQ ID NOs:22 and 23; SEQ ID NOs:24 and 25; SEQ ID NOs:26 and 27 or SEQ ID NOs:28 and 29; and (c) analyzing the results of the PCR for the presence of a larger or smaller DNA fragment, relative to a non-mutant fragment, as an indication that the subject exhibits the ramosa3 mutant genotype.

Another method included in the present invention is a method for selecting a first maize plant by marker assisted selection of a quantitative trait locus ("QTL") associated with branching of the tassel, ear or both, the method comprising: determining the presence of a locus in the first maize plant, wherein the locus hybridizes with a first nucleic acid that is genetically linked to a nucleic acid sequence having at least 90% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:15; and selecting the first maize plant comprising the locus that hybridizes with the first nucleic acid; thereby selecting the maize plant containing a QTL associated with branching of the tassel, ear or both.

As described above, the present invention includes, among other things, compositions and methods for modulating (i.e., increasing or decreasing) the level of polypeptides of the present invention in plants. In particular, the polypeptides of the present invention can be expressed at developmental stages, in tissues, and/or in quantities which are uncharacteristic of non-recombinantly engineered plants. In addition to altering (increasing or decreasing) branching, pollen shed or trehalose-6-phosphate phosphatase activity, it is believed that increasing or decreasing the level of polypeptides of the present invention in plants also can also have an impact on yield by altering the numbers of fruits and seeds produced by the inflorescences (due to extra branches) or by making plants more compact allowing them to be grown under stringent conditions, e.g., planted at high density or under adverse weather conditions, such as drought. Thus, the present invention also provides utility in such exemplary applications as improvement of yield or growth under stressful conditions.

The isolated nucleic acids and proteins and any embodiments of the present invention can be used over a broad range of plant types, particularly monocots such as the species of the Family Graminiae including Sorghum bicolor and Zea 55 mays. The isolated nucleic acid and proteins of the present invention can also be used in species from the genera: Cucurbita, Rosa, Vitis, Juglans, Fragaria, Lotus, Medicago, Onobrychis, Trifolium, Trigonella, Vigna, Citrus, Linum, Geranium, Manihot, Daucus, Arabidopsis, Brassica, Raphanus, Sinapis, Atropa, Capsicum, Datura, Hyoscyamus, Lycopersicon, Nicotiana, Solanum, Petunia, Digitalis, Majorana, Ciahorium, Helianthus, Lactuca, Bromus, Asparagus, Antirrhinum, Heterocallis, Nemesis, Pelargonium, Panieum, Pennisetum, Ranunculus, Senecio, Salpiglossis, Cucumis, Browaalia, Glycine, Pisum, Phaseolus, Lolium, Oryza, Avena, Hordeum, Secale, Triticum, Bambusa, Dendrocalamus, and Melocanna.

### **EXAMPLES**

The present invention is further illustrated in the following Examples, in which parts and percentages are by weight and degrees are Celsius, unless otherwise stated. It should be 5 understood that these Examples, while indicating preferred embodiments of the invention, are given by way of illustration only. From the above discussion and these Examples, one skilled in the art can ascertain the essential characteristics of this invention, and without departing from the spirit and scope 10 thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions. Thus, various modifications of the invention in addition to those shown and described herein will be apparent to those skilled in the art from the foregoing description. Such modifications 15 are also intended to fall within the scope of the appended claims.

### Example 1

### Phenotypic Analysis of ra3 Mutants

A mutant line with branched inflorescences was isolated in a non-targeted Mutator (Mu) transposon tagging family, and found to be an allele of ramosa3 (ra3). Although ra3 is a 25 classical mutant of maize, first described in 1954 by H. S. Perry (see also, Table 1 of Veit et al. Plant Cell 5:1205-1215 (1993)), it had not been characterized in detail. Only the mature inflorescence phenotype had been reported, and there was some confusion about the map location, as explained 30 below in Example 2.

To analyze ra3 mutant phenotypes, ra3 reference allele plants (ra3-ref; Maize Genetics CoOp Stock Center) were introgressed into B73 for at least 3 generations. During vegetative development, no differences were observed in ra3 35 plants compared to wild type sibs. In the inflorescence stage, ra3 mutants had irregular long branches in the ears, whereas wild type sib ears had a more compact and organized rachis. Also, irregular seed rows were present in contrast to the neatly shown on FIG. 1A-FIG. 1D, wild-type ear (FIG. 1A) has nicely arranged rows and no long branches, whereas ra3 mutant ears (FIG. 1B) have long branches and irregular rows of kernels. Occasionally, ra3 ears are covered in long branches (FIG. 1B, right). Wild type tassels normally have 45 long branches at their base (FIG. 1C), and ra3 mutant tassels (FIG. 1D) have more branches.

Mutant ra3 ears also had "upside-down" or inverted embryo orientations, which may indicate indeterminacy in the spikelet axis. These defects in ra3 ears were usually seen 50 only at the base, though occasionally the ears were irregularly branched along their whole length (FIG. 1B). As in the ear, ra3 tassels had more branches than wild-type tassels, although overall the developmental defects appeared to be milder than in the ears.

To determine how these defects in the mature inflorescences arise, scanning electron microscopy (SEM) was used to follow early ear and tassel development. The development of ears is described as follows. During the vegetative to inflorescence transition stage, there was no difference between ra3 60 and wild-type (FIG. 2A, FIG. 2E), and the ra3 inflorescence meristem (IM) initiated spikelet pair meristems (SPMs) as in wild-type (FIG. 2B, FIG. 2F). The first defects that were observed in immature ra3 ears were enlarged and irregular sized SPMs, when the ear primordia were around 1.5 mm 65 long. Slightly later in development, when the ear primordia were around 2 mm long, the conversion of SPMs to indeter34

minate meristems that produce additional SPMs was observed (FIG. 2F, arrow 1). Because this SPM produced additional SPMs, we chose to call it "branch meristem\*" (BM\*), to reflect its similarity to the BMs at the base of normal tassels. As ear development proceeded, the ra3 SPMs made 3-4 glumes before the conversion to a BM\* (FIG. 2G, arrows 2), while wild-type SMs made only 2 glumes that subtended the SM (arrows 2, FIG. 2C). Sometimes, floral meristems (FMs), rather than SMs, were produced inside these extra glumes in ra3 mutants (FIG. 2G). In summary, the SPMs that converted to BM\* in ra3 ears had two possible identities, SPM\* or a mixture of SPM and SM (SPM\*+SM\*). In this scheme, SPM\* produced several glumes containing only SPMs and SMs, whereas "SPM\*+SM\*" produced several glumes subtending FMs.

Mutant ra3 SMs also showed other types of identity defects. For example, they often made multiple FMs (arrows 3, FIG. 2H), whereas wild-type SMs produce only two FMs. Mutant ra3 SMs can even convert to BM\* identity after mak-20 ing several FMs. As in mature ears (FIG. 1B), usually only the meristems in the lower half of the ear showed these defects.

In ra3 tassels, similar developmental defects as in ra3 ears were observed. For example, they also produced more indeterminate SPMs. This resulted in about double the number of long branches in ra3 tassels (wild-type 6.8±1.4; ra3 13.6±2.8 branches).

In summary, ra3 ears and tassels showed a range of phenotypic defects; a summary for the ear is presented in FIG. 3. The developmental analysis showed that in general RA3 functions to impose determinacy and identity on the different meristem types in the inflorescences. Although the Ns are normal, the SPMs, SMs and FMs are all more indeterminate in ra3 mutants compared to wild type.

### Example 2

### Mapping and Isolation of ra3

According to the maize genetic map available, in 2004, at organized rows in wild-type ears. See FIG. 1A-FIG. 1D. As 40 the Maize Genetics and Genomics Database, ra3 was listed as being mapped to chromosome 4; however, we were unable to reproduce those results. To address this discrepancy, ra3 and sib DNAs were provided for analysis by the Missouri Maize Mapping Project [Coe, E., Cone, K., McMullen, M., Chen, S. S., Davis, G., Gardiner, J., Liscum, E., Polacco, M., Paterson, A., Sanchez-Villeda, H., Soderlund, C., and Wing, R., Access to the maize genome: an integrated physical and genetic map. Plant Physiol, 2002. 128(1): p. 9-12.].

> Using bulk segregant analysis, ra3 was mapped to chromosome 7, bin 4.

For more detailed mapping studies, larger mapping populations were constructed using the ra3-ref allele and an allele ("ra3-fea1") that was isolated from a Mu line carrying a fasciated ear mutant (feat, [Jackson, D. and Hake, S., The 55 genetics of ear fasciation in maize. Maize Genetics Cooperation Newsletter, 1999. 73: p. 2]).

The ra3 and fea1 mutations segregated independently in this line, indicating that these mutations are in different genes. F2s of each ra3 allele crossed to B73 were made, and highresolution mapping was conducted using simple sequence repeat (SSR), restriction fragment length polymorphism (RFLP), cleaved amplified polymorphic sequences (CAPS) and derived CAPS (dCAPS) markers (FIG. 4A).

By analyzing 74 ra3-ref mutants in the F2, one recombinant between marker csu597 (SEQ ID NOs:1 & 2) and ra3 and two recombinants in different individuals between marker umc1412 (SEQ ID NOs:3 & 4) and ra3 were identi-

fied, placing the ra3 locus between these two markers. To further delimit the ra3 region, a larger number of recombinants were screened, and new CAPS markers, a14 (SEQ ID NOs:5 & 6) and n20 (SEQ ID NOs:7 & 8) were created using BAC end sequences covering part of the ra3 region. DNA amplified from ra3-ref and B73 using these sets of primers gave polymorphisms when digested with Fok1 for a14 and HindIII for n20. Nine recombinants out of 873 ra3 mutants between a14 and ra3 and 10 recombinants between n20 and ra3 were obtained. The number of cross overs indicated that the genetic distance between ra3 and a14 was 0.7+/-0.2 cM and the genetic distance between ra3 and n20 was 0.6+/-0.2

This region of the maize genome was covered by three BAC clones, c0387K01, b0505C08 and b0063D15 [Cone, K. C. et al., Genetic, physical, and informatics resources for maize. On the road to an integrated map. Plant Physiol, 2002. 130(4): p. 1598-605]. New markers were made from these BACs by screening for non-repetitive DNA fragments. 20 TPPs, AtTPPA and AtTPPB, from Arabidopsis, and the A-Southern blots were made of each BAC clone digested with several restriction enzymes, and the blot was probed first with maize genomic DNA, and after imaging, probed again with the BAC DNA. Upon comparison of the two blot images, bands were identified that had a signal with the BAC hybrid- 25 ization but not with total genomic DNA hybridization. These bands were cataloged as being non-repetitive, and designated as "cold bands" (cb, FIG. 4A). These cold bands were used either as RFLP probes or, after sequencing, were converted into d-CAPS markers. The d-CAPS marker, cb.g1E, was 30 made from the sequence of cold band e; the forward and reverse primers for cb.g1E are given as SEQ ID NO:9 and SEQ ID NO:10, respectively. Using these additional markers, it was determined that the ra3 locus was positioned on the BAC c0387K01 (FIG. 4A).

The nucleotide sequence of BAC c0387K01 was determined and this sequence information was used to design primers for amplification of DNA from the recombinants identified earlier. NS346 (SEQ ID NO:11) and NS347 (SEQ ID NO:12) were one primer pair; NS362 (SEQ ID NO:13) 40 and NS363 (SEQ ID NO:14) was a second primer pair. These two primer pairs were used to generate PCR product length polymorphisms, which were used to delimit the RA3 locus to a single predicted gene (FIG. 4B).

### Example 3

### RA3 and SRA Gene Structure and Phylogenetic Analysis

The nucleotide sequence shown in SEQ ID NO:15 was deduced from BAC c038K01, and encodes the RA3 gene with 3 kb of sequence upstream (5') of the ATG initiation codon, and 7.5 kb downstream (3') of the TGA stop codon. Note that exons in SEQ ID NO:15 are displayed only for the region 55 from the start codon to the stop codon, and are not shown for the 5' or 3' Untranslated Regions (5'- and 3'-UTRs).

The cDNA sequence corresponding to the RA3 region was isolated by reverse transcription of poly(A)-RNA followed by PCR. The Quiagen OneStep RT-PCR kit was used according 60 to the manufacturers specifications. The primer set used was NS432 (SEQ ID NO:16) and NS411 (SEQ ID NO:17). SEQ ID NO:18 is the nucleotide sequence of the protein-coding region deduced from the PCR product obtained using the NS432 and NS411 primers. The corresponding amino acid sequence of the RAMOSA3 polypeptide is shown as SEQ ID NO:19.

36

The RA3 gene encodes a predicted protein of 361 amino acids with significant similarity to trehalose-6-phosphate phosphatases (TPPs). The predicted polypeptide has a nonconserved N-terminal region of ~80 amino acids followed by the TPP domain which contains two "phosphatase boxes" (see FIG. 5A, region labeled "3") [Goddijn, O. J. and van Dun, K., Trehalose metabolism in plants. Trends Plant Sci, 1999. 4(8): p. 315-319; Thaller, M. C., Schippa, S., and Rossolini, G. M., Conserved sequence motifs among bacterial, eukaryotic, and archaeal phosphatases that define a new phosphohydrolase superfamily. Protein Sci, 1998. 7(7): p. 1647-52; Vogel, G., Aeschbacher, R. A., Muller, J., Boller, T., and Wiemken, A., Trehalose-6-phosphate phosphatases from Arabidopsis thaliana: identification by functional complementation of the yeast tps2 mutant. Plant J, 1998. 13(5): p. 673-83]. FIG. 5A contains an "A-domain" (SEQ ID NO:45) and a "B-domain" (SEQ ID NO:46), as designated by Vogel et al. (1998) Plant J 13(5):673-83.

RA3 is very similar in the TPP domain to the functional and B-domains of RA3 and AtTPPB are identical. In a comparison of plant TPP proteins to the corresponding yeast protein, RA3 is actually more similar to yeast TPS2 than is the Arabidopsis AtTPPA (20% vs. 16% identity).

Adjacent to RA3 there was a highly similar TPP gene, which we have designated SISTER OF RAMOSA3 (SRA). The genomic DNA sequence containing the SRA gene is shown in SEQ ID NO:47. The nucleotide sequence of the protein-coding region of the SRA gene is shown in SEQ ID NO:48, and the corresponding amino acid sequence of the SRA polypeptide is shown in SEQ ID NO:49. A cDNA clone, my.cs1.pk0072.d4, was prepared from RNA isolated from the leaf and sheath of 5-week old Zea mays L. plants, and it contains a fragment of the SRA gene. Part of the nucleotide sequence of the cDNA insert of clone my.cs1.pk0072.d4 is presented in SEQ ID NO:50.

In the region of conserved synteny in rice, only a single rice TPP gene, gi33146623 (SEQ ID NO:43), is found. RA3 and SRA have 60.4 and 59.3% overall sequence identity, respectively, with the rice TPP (Table 1). Genbank and the maize sequence assemblies available at the Maize Genetics and Genomics Database and at The Institute for Genomic Research Maize Database were examined for the presence of closely related homologs to RA3 and SRA. Because the 45 maize proteins are not yet annotated we named them "ZmRA3 Like" ("ZmRA3L").

A phylogenetic analysis of TPP genes from Arabidopsis, rice and maize is shown in a neighbor-joining tree (FIG. 5B). [Swofford, D., PAUP—A COMPUTER-PROGRAM FOR 50 PHYLOGENETIC INFERENCE USING MAXIMUM PARSIMONY. JOURNAL OF GENERAL PHYSIOLOGY, 1993. 102: p. A9] The tree indicates that RA3, SRA and gi33146623 (SEQ ID NO:43) are most closely related, and RA3 and SRA are likely paralogs. TPPB, a functional TPP from Arabidopsis (At1g78090; SEQ ID NO:53 corresponding to NCBI GI NO. 2944180) is the most closely related Arabidopsis protein.

FIGS. 6A-6D show a sequence alignment of the amino acid sequences for the following trehalose-6-phosphate phosphatases: RA3 (SEQ ID NO:19); SRA (SEQ ID NO:49); rice TPP (SEQ ID NO:51); Arabidopsis TPPA (SEQ ID NO:52); Arabidopsis TPPB (SEQ ID NO:53); corn TPP (SEQ ID NO:54); and soybean TPP (SEQ ID NO:55). Also shown are alignments with two truncated forms of Arabidopsis TPPA and TPPB, in which the N-terminal 91 amino acids have been removed from each. An asterisk above an amino acid residue indicates that the position is totally conserved among the

given SEQ ID NOs, with respect to the Arabidopsis thaliana AtTPPB sequence. Below the sequences are shown two domains, A and B, that are conserved among trehalose-6phosphate phosphatases, as described in Vogel et al. (1998) Plant J 13(5):673-683. The given sequence for each conserved domain is taken from the Arabidopsis thaliana AtTPPB amino acid sequence at these positions. FIGS. 6A-6D indicate that regions of high sequence similarity are located in the carboxy-terminal 70% of the consensus sequence. Vogel et al. have noted that the AtTPPA and AtTPPB proteins have high sequence conservation to each other except for the amino-terminal 100 amino acids, which they note have features in common with chloroplast transit peptides. Vogel et al. have shown enzyme activity for 15 AtTPPA, AtTPPB, and a truncated AtTPPA polypeptide that is missing the first 91 amino acids.

The data in Table 1 show the percent identity for each pair of amino acid sequences from the group consisting of SEQ ID NOs:19, 49, 51, 52, 53, 54, 55, an enzymatically active fragment of SEQ ID NO:52 (AtTPPA) in which the first 91 amino acids are missing (Vogel et al. (1998) *Plant J* 13(5):673-683), and a corresponding truncated AtTPPB polypeptide in which the first 91 amino acids have been removed. From this comparison of percent identities, the RA3 and SRA polypeptides were found to have a higher percent identity to the AtTPPB truncated polypeptide, than the AtTPPA truncated polypeptide.

<sup>\*52</sup>t refers to a truncation of the AtTPPA polypeptide (SEQ ID NO: 52), in which 91 amino acids have been removed from the amino terminus.

Example 4

## Sequence Analysis of ra3 Mutant Alleles

To confirm that the predicted locus encodes RA3, seven ra3 alleles were sequenced. These ra3 alleles were either preexisting alleles or were isolated from targeted screens. Each had a lesion in the candidate gene, indicating that it encodes RA3 (Table 2).

Coding regions of mutant alleles ra3-ref, ra3-fea1, ra3-EV, 60 ra3-NI, ra3-bre, ra3-JL and ra3-NS were sequenced following amplification using the following primer sets: 5'UTR-exon2 forward and reverse primers (SEQ ID NO:20 & 21, respectively); exon3-exon4 forward and reverse primers (SEQ ID NO:22 & 23, respectively); exon5-exon7 forward 65 and reverse primers (SEQ ID NO:24 & 25, respectively); exon8-exon10 forward and reverse primers (SEQ ID NO:26

& 27, respectively); and exon11-3'UTR forward and reverse primers (SEQ ID NO:28 & 29, respectively).

The ra3-ref mutant allele has a 4 bp insertion in exon7 (SEQ ID NO:30). This results in a frame-shift after amino acid 249 and a premature stop codon after 305 amino acids. The predicted ra3-ref polypeptide is shown in SEQ ID NO:31.

The ra3-fea1 mutant allele contains the following two mutations: 1) an insertion of an ILS-1-like transposon element in the 5'-UTR region of the ra3-fea1 mutant gene (SEQ ID NO:32); and 2) a 4 bp insertion in the coding sequence of exon7 (SEQ ID NO:33), leading to a frame-shift after amino acid 258 and a premature stop codon after 305 amino acids. The predicted amino acid sequence of the ra3-fea1 polypeptide is shown in SEQ ID NO:34.

The ra3-EV mutant allele carries a 4 bp insertion in exon6 (SEQ ID NO:35). This results in a frame-shift after amino acid 224 and a premature stop codon after 305 amino acids. The predicted amino acid sequence of the ra3-EV polypeptide is shown in SEQ ID NO:36.

The ra3-NI mutant allele has an insertion of 141 bp in exon10 (SEQ ID NO:37), leading to a different protein sequence after amino acid 333 and a premature stop codon after 335 amino acids. The predicted amino acid sequence of the ra3-NI polypeptide is shown in SEQ ID NO:38.

The ra3-bre mutant allele has a 10 bp insertion between exon6 and exon7 (SEQ ID NO:39), leading to a frame-shift after amino acid 241 and a premature stop codon after 243 amino acids. The predicted amino acid sequence of the ra3-bre polypeptide is shown in SEQ ID NO:40.

The ra3-JL mutant allele has a deletion and rearrangement in exon6 (SEQ ID NO:41), leading to a different protein sequence after amino acid 217 and a premature stop codon after 246 amino acids. The predicted amino acid sequence of the ra3-JL polypeptide is shown in SEQ ID NO:42.

The ra3-NS mutant allele has a 2 bp insertion in exon6 (SEQ ID NO:43), leading to a frame-shift after amino acid 222 and a premature stop codon after 299 amino acids. The predicted amino acid sequence of the ra3-NS polypeptide is shown in SEQ ID NO:44.

The nature of some alleles was unusual, for example some alleles obtained from transposon screens had insertions of only a few nucleotides, possibly reflecting abortive transposition events. Both ra3-ref and ra3-fea1 had a 4 bp insertion in exon 7, at different positions, and ra3-fea1 also contained a transposon in the 5' region. In each allele the mutation caused a frame-shift, and a premature stop codon.

TABLE 2

	Seven ra3 Alleles Have Mutations in the Candidate Locus.								
Allele	Source	Lesion							
ra3-ref	Maize Genetics Stock Center	4 bp insertion into exon7							
ra3-fea1	Mu transposon stock (D. Jackson)	~2 kb ILS-like transposon between TATA box and exon1; 4 bp insertion into exon7							
ra3-EV	Ac-Ds stock (E. Vollbrecht)	4 bp insertion into exon6							
ra3-NI	EMS screen (N. Inada)	141 bp insertion into exon10							
ra3-bre	Unknown (E. Irish)	10 bp insertion in cDNA, between exon6 and exon7							
ra3-JL ra3-NS	Mu transposon screen Spm transposon screen	Deletion and rearrangement in exon6 2 bp insertion into exon6							

Each mutant allele has a stop codon before the second phosphatase box, except for ra3-NI, which has a stop codon

acids have been removed from the amino terminus.

\*\*53 trefers to a truncation of the AtTPPB polypeptide (SEQ ID NO: 53), in which 91 amino acids have been removed from the amino terminus.

after the second phosphatase box. This correlates with phenotype, since ra3-NI mutants have the mildest phenotype.

#### Example 5

#### **RA3** Gene Expression Profile

RT-PCR analysis was used to determine where and when during development RA3 and SRA are expressed. First, RT-PCR primers were tested on the ra3 alleles. In mRNA isolated from 1 cm long ear primordia, a transcript was detected in wild type (B73) ears and in ra3-EV, ra3-NI and ra3-bre. However, no transcript was detected in mRNA from ra3-fea1 immature ears, indicating the specificity of these primers for RA3 (FIG. 7A). During development, RA3 was expressed 15 most strongly during early female and male inflorescence development, and peaked at around 2-5 mm in ear and tassel development. At this stage, SPM and SM are being initiated on the developing inflorescences. Very low levels of RA3 transcript were detected in root or vegetative apex, and were 20 not detected in leaf (FIG. 7B). On the other hand, SRA was expressed more evenly throughout development, with a slightly higher expression in root and larger tassel primordia (FIG. 7B).

Additionally, in situ hybridization was used to determine if 25 RA3 expression was spatially regulated during early inflorescence development. RA3 expression was observed in ear primordia in a cup-shaped group of cells at the base of SPMs, SMs and FMs, and at the boundary between upper and lower florets (FIG. 8A-FIG. 8F). This expression is specific for RA3, as it was not seen in ra3-ref ears. Together with the developmental analysis, this highly restricted expression patter suggests an important developmental role for RA3 in maize inflorescence development.

In summary, the RA3 gene of maize is expressed preferentially in restricted domains at early stages of inflorescence development. Phenotypic analysis suggests that RA3 acts at this stage to restrict the determinacy and identity of different meristem types in the inflorescence.

## Example 6

## Prophetic Example

## Expression of Recombinant DNA in Monocot Cells

A recombinant DNA construct comprising a cDNA encoding the instant polypeptides in sense orientation with respect to the maize 27 kD zein promoter that is located 5' to the cDNA fragment, and the 10 kD zein 3' end that is located 3' to 50 the cDNA fragment, can be constructed. The cDNA fragment of this gene may be generated by polymerase chain reaction (PCR) of the cDNA clone using appropriate oligonucleotide primers. Cloning sites (NcoI or SmaI) can be incorporated into the oligonucleotides to provide proper orientation of the 55 DNA fragment when inserted into the digested vector pML103 as described below. Amplification is then performed in a standard PCR. The amplified DNA is then digested with restriction enzymes NcoI and SmaI and fractionated on an agarose gel. The appropriate band can be isolated from the gel 60 and combined with a 4.9 kb NcoI-SmaI fragment of the plasmid pML103. Plasmid pML103 has been deposited under the terms of the Budapest Treaty at ATCC (American Type Culture Collection, 10801 University Blvd., Manassas, Va. 20110-2209), and bears accession number ATCC 97366. 65 The DNA segment from pML103 contains a 1.05 kb SalI-NcoI promoter fragment of the maize 27 kD zein gene and a

40

0.96 kb SmaI-SalI fragment from the 3' end of the maize 10 kD zein gene in the vector pGem9Zf(+) (Promega). Vector and insert DNA can be ligated at 15° C. overnight, essentially as described (Maniatis). The ligated DNA may then be used to transform *E. coli* XL1-Blue (*Epicurian Coli* XL-1 Blue<sup>TM</sup>; Stratagene). Bacterial transformants can be screened by restriction enzyme digestion of plasmid DNA and limited nucleotide sequence analysis using the dideoxy chain termination method (Sequenase<sup>TM</sup> DNA Sequencing Kit; U.S. Biochemical). The resulting plasmid construct would comprise a recombinant DNA construct encoding, in the 5' to 3' direction, the maize 27 kD zein promoter, a cDNA fragment encoding the instant polypeptides, and the 10 kD zein 3' region.

The recombinant DNA construct described above can then be introduced into corn cells by the following procedure. Immature corn embryos can be dissected from developing caryopses derived from crosses of the inbred corn lines H99 and LH132. The embryos are isolated 10 to 11 days after pollination when they are 1.0 to 1.5 mm long. The embryos are then placed with the axis-side facing down and in contact with agarose-solidified N6 medium (Chu et al. (1975) *Sci. Sin. Peking* 18:659-668). The embryos are kept in the dark at 27° C. Friable embryogenic callus consisting of undifferentiated masses of cells with somatic proembryoids and embryoids borne on suspensor structures proliferates from the scutellum of these immature embryos. The embryogenic callus isolated from the primary explant can be cultured on N6 medium and sub-cultured on this medium every 2 to 3 weeks.

The plasmid, p35S/Ac (obtained from Dr. Peter Eckes, Hoechst Ag, Frankfurt, Germany) may be used in transformation experiments in order to provide for a selectable marker. This plasmid contains the Pat gene (see European Patent Publication 0 242 236) which encodes phosphinothricin acetyl transferase (PAT). The enzyme PAT confers resistance to herbicidal glutamine synthetase inhibitors such as phosphinothricin. The pat gene in p35S/Ac is under the control of the 35S promoter from cauliflower mosaic virus (Odell et al. (1985) Nature 313:810-812) and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of Agrobacterium tumefaciens.

The particle bombardment method (Klein et al. (1987) Nature 327:70-73) may be used to transfer genes to the callus culture cells. According to this method, gold particles (1 µm in diameter) are coated with DNA using the following tech-45 nique. Ten  $\mu g$  of plasmid DNAs are added to 50  $\mu L$  of a suspension of gold particles (60 mg per mL). Calcium chloride (50 µL of a 2.5 M solution) and spermidine free base (20 μL of a 1.0M solution) are added to the particles. The suspension is vortexed during the addition of these solutions. After 10 minutes, the tubes are briefly centrifuged (5 sec at 15,000 rpm) and the supernatant removed. The particles are resuspended in 200 µL of absolute ethanol, centrifuged again and the supernatant removed. The ethanol rinse is performed again and the particles resuspended in a final volume of 30 μL of ethanol. An aliquot (5 µL) of the DNA-coated gold particles can be placed in the center of a Kapton<sup>TM</sup> flying disc (Bio-Rad Labs). The particles are then accelerated into the corn tissue with a Biolistic™ PDS1000/He (Bio-Rad Instruments, Hercules Calif.), using a helium pressure of 1000 psi, a gap distance of 0.5 cm and a flying distance of 1.0 cm.

For bombardment, the embryogenic tissue is placed on filter paper over agarose-solidified N6 medium. The tissue is arranged as a thin lawn and covered a circular area of about 5 cm in diameter. The petri dish containing the tissue can be placed in the chamber of the PDS1000/He approximately 8 cm from the stopping screen. The air in the chamber is then evacuated to a vacuum of 28 inches of Hg. The macrocarrier

is accelerated with a helium shock wave using a rupture membrane that bursts when the He pressure in the shock tube reaches 1000 psi.

Seven days after bombardment the tissue can be transferred to N6 medium that contains bialophos (5 mg per liter) and 5 lacks casein or proline. The tissue continues to grow slowly on this medium. After an additional 2 weeks the tissue can be transferred to fresh N6 medium containing bialophos. After 6 weeks, areas of about 1 cm in diameter of actively growing callus can be identified on some of the plates containing the 10 bialophos supplemented medium. These calli may continue to grow when sub-cultured on the selective medium.

Plants can be regenerated from the transgenic callus by first transferring clusters of tissue to N6 medium supplemented with 0.2 mg per liter of 2,4-D. After two weeks the tissue can be transferred to regeneration medium (Fromm et al. (1990) *Bio/Technology* 8:833-839).

### Example 7

#### Prophetic Example

## Expression of Recombinant DNA in Dicot Cells

An expression cassette composed of the promoter from the 25 B-conglycinin or glycinin genes (Chen, Z-L, et al. (1988) EMBO J. 7:297-302), 5-prime to the cDNA fragment, can be constructed and be used for expression of the instant polypeptides in transformed soybean. The pinll terminator can be placed 3-prime to the cDNA fragment. Such construct may be 30 used to overexpress the instant polypeptides. It is realized that one skilled in the art could employ different promoters and/or 3-prime end sequences to achieve comparable expression results

The cDNA fragment of this gene may be generated by 35 polymerase chain reaction (PCR) of the cDNA clone using appropriate oligonucleotide primers. Cloning sites can be incorporated into the oligonucleotides to provide proper orientation of the DNA fragment when inserted into the expression vector. Amplification is then performed as described 40 above, and the isolated fragment is inserted into a pUC18 vector carrying the seed expression cassette.

Soybean embryos may then be transformed with the expression vector comprising sequences encoding the instant polypeptides. To induce somatic embryos, cotyledons, 3-5 45 mm in length dissected from surface sterilized, immature seeds of the soybean cultivar A2872, can be cultured in the light or dark at 26° C. on an appropriate agar medium for 6-10 weeks. Somatic embryos, which produce secondary embryos, are then excised and placed into a suitable liquid 50 medium. After repeated selection for clusters of somatic embryos which multiplied as early, globular staged embryos, the suspensions are maintained as described below.

Soybean embryogenic suspension cultures can be maintained in 35 mL liquid media on a rotary shaker, 150 rpm, at 55 26° C. with florescent lights on a 16:8 hour day/night schedule. Cultures are subcultured every two weeks by inoculating approximately 35 mg of tissue into 35 mL of liquid medium.

Soybean embryogenic suspension cultures may then be transformed by the method of particle gun bombardment 60 (Klein et al. (1987) *Nature* (London) 327:70-73, U.S. Pat. No. 4,945,050). A DuPont Biolistic™ PDS1000/HE instrument (helium retrofit) can be used for these transformations.

A selectable marker gene which can be used to facilitate soybean transformation is a chimeric gene composed of the 65 35S promoter from cauliflower mosaic virus (Odell et al. (1985) *Nature* 313:810-812), the hygromycin phosphotrans-

42

ferase gene from plasmid pJR225 (from *E. coli*; Gritz et al. (1983) *Gene* 25:179-188) and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of *Agrobacterium tumefaciens*. The seed expression cassette comprising the phaseolin 5' region, the fragment encoding the instant polypeptides and the phaseolin 3' region can be isolated as a restriction fragment. This fragment can then be inserted into a unique restriction site of the vector carrying the marker gene.

To 50  $\mu L$  of a 60 mg/mL 1  $\mu m$  gold particle suspension is added (in order): 5  $\mu L$  DNA (1  $\mu g/\mu L$ ), 20  $\mu L$  spermidine (0.1M), and 50  $\mu L$  CaCl<sub>2</sub> (2.5M). The particle preparation is then agitated for three minutes, spun in a microfuge for 10 seconds and the supernatant removed. The DNA-coated particles are then washed once in 400  $\mu L$  70% ethanol and resuspended in 40  $\mu L$  of anhydrous ethanol. The DNA/particle suspension can be sonicated three times for one second each. Five  $\mu L$  of the DNA-coated gold particles are then loaded on each macro carrier disk.

Approximately 300-400 mg of a two-week-old suspension culture is placed in an empty 60×15 mm petri dish and the residual liquid removed from the tissue with a pipette. For each transformation experiment, approximately 5-10 plates of tissue are normally bombarded. Membrane rupture pressure is set at 1100 psi and the chamber is evacuated to a vacuum of 28 inches mercury. The tissue is placed approximately 3.5 inches away from the retaining screen and bombarded three times. Following bombardment, the tissue can be divided in half and placed back into liquid and cultured as described above

Five to seven days post bombardment, the liquid media may be exchanged with fresh media, and eleven to twelve days post bombardment with fresh media containing 50 mg/mL hygromycin. This selective media can be refreshed weekly. Seven to eight weeks post bombardment, green, transformed tissue may be observed growing from untransformed, necrotic embryogenic clusters. Isolated green tissue is removed and inoculated into individual flasks to generate new, clonally propagated, transformed embryogenic suspension cultures. Each new line may be treated as an independent transformation event. These suspensions can then be subcultured and maintained as clusters of immature embryos or regenerated into whole plants by maturation and germination of individual somatic embryos.

## Example 8

#### Prophetic Example

## Expression of Recombinant DNA in Microbial Cells

The cDNAs encoding the instant polypeptides can be inserted into the T7 *E. coli* expression vector pBT430. This vector is a derivative of pET-3a (Rosenberg et al. (1987) *Gene* 56:125-135) which employs the bacteriophage T7 RNA polymerase/T7 promoter system. Plasmid pBT430 is constructed by first destroying the EcoRI and HindIII sites in pET-3a at their original positions. An oligonucleotide adaptor containing EcoRI and Hind III sites is inserted at the BamHI site of pET-3a. This creates pET-3aM with additional unique cloning sites for insertion of genes into the expression vector. Then, the NdeI site at the position of translation initiation is converted to an NcoI site using oligonucleotide-directed mutagenesis. The DNA sequence of pET-3aM in this region, 5'-CATATGG, is converted to 5'-CCCATGG in pBT430.

Plasmid DNA containing a cDNA may be appropriately digested to release a nucleic acid fragment encoding the pro-

tein. This fragment may then be purified on a 1% low melting agarose gel. Buffer and agarose contain 10 µg/ml ethidium bromide for visualization of the DNA fragment. The fragment can then be purified from the agarose gel by digestion with GELase<sup>TM</sup> (Epicentre Technologies, Madison, Wis.) according to the manufacturer's instructions, ethanol precipitated, dried and resuspended in 20 uL of water. Appropriate oligonucleotide adapters may be ligated to the fragment using T4 DNA ligase (New England Biolabs (NEB), Beverly, Mass.). The fragment containing the ligated adapters can be purified from the excess adapters using low melting agarose as described above. The vector pBT430 is digested, dephosphorylated with alkaline phosphatase (NEB) and deproteinized with phenol/chloroform as described above. The prepared 15 vector pBT430 and fragment can then be ligated at 16° C. for 15 hours followed by transformation into DH5 electrocompetent cells (GIBCO BRL). Transformants can be selected on agar plates containing LB media and 100 μg/mL ampicillin. Transformants containing the gene encoding the instant 20 polypeptides are then screened for the correct orientation with respect to the T7 promoter by restriction enzyme analy-

For high level expression, a plasmid clone with the cDNA insert in the correct orientation relative to the T7 promoter can  $^{25}$ be transformed into E. coli strain BL21(DE3) (Studier et al. (1986) J. Mol. Biol. 189:113-130). Cultures are grown in LB medium containing ampicillin (100 mg/L) at 25° C. At an optical density at 600 nm of approximately 1, IPTG (isopropylthio-β-galactoside, the inducer) can be added to a final concentration of 0.4 mM and incubation can be continued for 3 h at 25° C. Cells are then harvested by centrifugation and re-suspended in 50 µL of 50 mM Tris-HCl at pH 8.0 containing 0.1 mM DTT and 0.2 mM phenyl methylsulfonyl fluoride. A small amount of 1 mm glass beads can be added and the mixture sonicated 3 times for about 5 seconds each time with a microprobe sonicator. The mixture is centrifuged and the protein concentration of the supernatant determined. One µg of protein from the soluble fraction of the culture can be 40 separated by SDS-polyacrylamide gel electrophoresis. Gels can be observed for protein bands migrating at the expected molecular weight.

#### Example 9

## RAMOSA3 Protein-In Vitro

Trehalose-6-Phosphate Phosphatase Activity

Protein expression and in vitro phosphatase assays. To produce recombinant proteins for in vitro phosphatase assays, *E. coli* expression vectors were constructed containing polynucleotides encoding either the RA3 full-length protein, the RA3 TPP-domain fragment or the RA3 N-terminal fragment. DNA fragments encoding either the RA3 full-length protein, the RA3 TPP-domain fragment or the RA3 N-terminal fragment were amplified, respectively, using the following primer pairs:

RA3 Full-Length Protein:

```
NS487 (SEQ ID NO: 56): CGAGCCATGACGAAGCAC and NS429 (SEQ ID NO: 57): ATAAGCGCCTCTTTGCTGTTG;
```

44

RA3 TPP-Domain Fragment:

```
NS483 (SEQ ID NO: 58): GGCGACTGGATGGAGAAGCA and S429 (SEQ ID NO: 57): ATAAGCGCCTCTTTGCTGTTG. RA3 N-Terminal Fragment:
```

NS485 (SEQ ID NO: 59): GTGCGCGGATCCAGCCATGACGAAGCACGCCGCCTACTC and

NS488 (SEQ ID NO: 60): CTTCTCGAATTCTCAGCCGTGCTCGGCGTCGGCG.

PCR fragments were cloned into the vector pCR T7/NT-TOPO, which introduces an N-terminal histidine tag into the recombinant protein (Invitrogen). His-tagged recombinant proteins were expressed in E. coli and purified by a batch purification method (Qiagen). The proteins were used at a concentration of 70 ng/µl for phosphatase assays using sugar phosphates (Sigma) at a concentration of 2 mM, or ser/thr phosphopeptide as described (Klutts, S. et al. "Purification, cloning, expression, and properties of mycobacterial trehalose-phosphate phosphatase" J Biol Chem 278:2093-2100 (2003)). Sugar phosphate phosphatase activity was measured using the following four sugar phosphates: trehalose-6-phosphate, glucose-6-phosphate, fructose-6-phosphate and sucrose-6-phosphate. Phosphate release was measured as OD<sub>600</sub> (serine/threonine phosphatase assay system, Promega).

His-tagged RA3 full-length protein (SEQ ID NO:61), Histagged RA3 TPP-domain fragment (SEQ ID NO:62) and the His-tagged *Mycobacterium tuberculosis* trehalose-6-phosphate phosphatase (Edavana et al., *Arch Biochem Biophys* 426:250-257 (2004)) each catalyzed phosphate release from trehalose-6-phosphate (T6P) but not from the other sugar phosphates or the ser/thr phosphopeptide used as a reporter of protein phosphatase activity (FIG. 9). The His-tagged RA3 N-terminal fragment (SEQ ID NO:63) had no phosphatase activity and the non-specific phosphatase, shrimp alkaline phosphatase (SAP; Roche Applied Science), showed phosphatase activity against all substrates (FIG. 9). This in vitro activity data supports the assignment of T6P phosphatase activity to the RA3 protein.

The His-tagged RA3 TPP-domain fragment (SEQ ID NO:62) consists of a 35-aa N-terminal region that contains six consecutive histidine residues, followed by amino acid residues 78-361 of the RA3 protein (SEQ ID NO:19). The in vitro activity data (FIG. 9) indicates that amino acid residues 78-361 of the RA3 protein are sufficient to convey T6P phosphatase activity.

## Example 10

## RAMOSA3 Protein—In Vivo

Trehalose-6-Phosphate Phosphatase Activity

60

Complementation of yeast tps2 mutant: To complement a yeast mutant deficient in trehalose-6-phosphate phosphatase, DNA fragments encoding RA3 full-length protein and RA3 TPP-domain fragment each were cloned into a yeast expression vector. DNA fragments encoding either the RA3 full-length protein or the RA3 TPP-domain fragment were amplified, respectively, using the following primer pairs:

RA3 Full-Length Protein:

```
NS489 (SEQ ID NO: 64):
AAGGAAAAAGCGGCCGCCCATGACGAAGCACGCCGCCTACTC
and
NS490 (SEQ ID NO: 65):
ACGAGGTCGTGCCGCCTCATGGTTGGCGCGCCCCCTTCT;
```

**RA3** TPP-Domain Fragment:

NS490 (SEQ ID NO: 65):

```
ACGAGGTCGTGCCTGCCGCTCATGGTTGGCGCCCCCTTCT and
```

NS500 (SEQ ID NO: 66): CGCGCCGCCGGCGGCGCACATGGACTGGATGGAGAAGCACCCGTC.

The DNA fragments encoding RA3 full-length protein and the RA3 TPP-domain fragment were cloned into a yeast shuttle vector, pFL6, in which high-level expression is driven by the phosphoglycerate kinase promoter (Minet, M., Dufour, M. E. & Lacroute, F. "Complementation of *Saccharomyces cerevisiae* auxotrophic mutants by *Arabidopsis thaliana* cDNAs" *Plant J* 2:417-422 (1992)). The *Arabidopsis* TPPB 25 gene was used as a positive control. The empty yeast vector

46

transformed into the yeast mutant served as a negative control. The constructs were transformed into the yeast strain YSH6.106.-8C, which has a deletion of the tps2 gene and hence lacks TPP activity. This mutant strain is sensitive to  $high \, temperature \, and \, salt \, concentrations \, (De Virgilio, C. \, et \, al. \,$ "Disruption of TPS2, the gene encoding the 100-kDa subunit of the trehalose-6-phosphate synthase/phosphatase complex in Saccharomyces cerevisiae, causes accumulation of trehalose-6-phosphate and loss of trehalose-6-phosphate phos-10 phatase activity" Eur. J. Biochem 212:315-323 (1993)). The yeast TPP mutant grows normally at 30° C., but has very slow growth at elevated temperature (40° C.), especially in the presence of an osmotic stress such as 1M NaCl. Transformed cells were assayed for growth on selective media at 40.5° C., 15 the non-permissive temperature, in the presence of 1M NaCl, as well as at 30° C.

RA3 full-length protein (SEQ ID NO:19) and RA3 TPP-domain fragment (SEQ ID NO:68) each rescued growth at the non-permissive temperature (FIG. 10). Consequently, RA3 protein functions as a T6P phosphatase in vivo.

The RA3 TPP-domain fragment (SEQ ID NO:68) expressed in the yeast mutant consists of a start methionine residue followed by amino acid residues 79-361 of the RA3 protein (SEQ ID NO:19). The data in FIG. 10 indicates that amino acid residues 79-361 of the RA3 protein are sufficient to convey T6P phosphatase activity in vivo.

The invention claimed is:

- 1. A recombinant DNA construct comprising a polynucleotide operably linked to a heterologous promoter that is functional in a plant, wherein the polynucleotide comprises:
  - (a) a nucleic acid sequence encoding a polypeptide having trehalose-6-phosphate phosphatase activity, wherein the polypeptide has an amino acid sequence of at least 90% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69; or
  - (b) a complement of the nucleotide sequence, wherein the complement and the nucleotide sequence consist of the same number of nucleotides and are 100% complementary.
- 2. A method for altering trehalose-6-phosphate phosphatase activity in a plant, comprising:
  - (a) introducing into a regenerable plant cell the recombinant DNA construct of claim 1 to produce a transformed plant cell; and
  - (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an alteration in trehalose-6-phosphate phosphatase activity, when compared to a control plant not comprising said recombinant DNA construct.

- 3. The method of claim 2, further comprising (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct.
- **4**. The method of claim **2**, wherein the transgenic plant exhibits an increase in trehalose-6-phosphate phosphatase activity.
- 5. A method for increasing environmental stress tolerance of a plant, comprising:
  - (a) introducing into a regenerable plant cell the recombinant DNA construct of claim 1 to produce a transformed plant cell; and
  - (b) regenerating a transgenic plant from said transformed plant cell, wherein said transgenic plant comprises in its genome said recombinant DNA construct and wherein said transgenic plant exhibits an increase in environmental stress tolerance, when compared to a control plant not comprising said recombinant DNA construct.
- **6**. The method of claim **5**, further comprising (c) obtaining a progeny plant derived from said transgenic plant, wherein said progeny plant comprises in its genome the recombinant DNA construct.
- 7. The method of claim 5, wherein said environmental stress is drought, and wherein said transgenic plant exhibits an increase in drought tolerance.

127

- **8**. The recombinant DNA of claim **1**, wherein the amino acid sequence of the polypeptide has at least 95% sequence identity, based on the Clustal V method of alignment, when compared to SEQ ID NO:19, 49, 68 or 69.
- 9. The recombinant DNA of claim 1, wherein the amino 5 acid sequence of the polypeptide comprises SEQ ID NO:19, 49, 68 or 69.
- 10. The recombinant DNA of claim 1, wherein the nucleotide sequence comprises SEQ ID NO:18, 48 or 67.
- 11. A plant or seed comprising the recombinant DNA construct of claim 1.
- $12.\,\mathrm{A}$  plant or seed comprising the recombinant DNA construct of claim 8.
- 13. A plant or seed comprising the recombinant DNA construct of claim 9.
- $14.\,\mathrm{A}$  plant or seed comprising the recombinant DNA construct of claim 10.
- 15. The plant or seed of claim 11, wherein the plant or seed is a maize plant or seed.
- **16**. The plant or seed of claim **12**, wherein the plant or seed 20 is a maize plant or seed.
- 17. The plant or seed of claim 13, wherein the plant or seed is a maize plant or seed.
- 18. The plant or seed of claim 14, wherein the plant or seed is a maize plant or seed.
  - 19. The method of claim 4, wherein the plant is maize.
  - 20. The method of claim 7, wherein the plant is maize.
